# SECTION 1

## INTRODUCTION

### 1-1. USING THE TR-7 SERVICE MANUAL

This manual is divided into several sections for clarity and ease of use. Each major section is written with the assumption that the preceding portions of the manual have been read and understood by the user.

Section 1 is introductory in nature, and provides a general discussion of operating theory, module location, troubleshooting techniques and tool requirements.

Section 2 contains complete information in each functional element of the TR-7. This information includes detailed circuit description, parts list, component location and schematic diagram. This section of the manual is divided by functional element such as circuit board, module, chassis, etc. for the purpose of rapid circuit, component and problem identification.

Section 3 is a complete alignment procedure for the TR-7, and includes test equipment requirements/recommendations and test point locations.

### 1-2. LOCATING A MALFUNCTION

The modular design of the TR-7 allows easy exchange of most of the printed circuit boards. All modules are easily removed with the exception of the low-pass and high-pass filter modules, the PTO, and the power amplifier.

The first step in troubleshooting the TR-7 should be isolation of the malfunction to the module or board level. Refer to Section 1-3 for a general discussion of theory of operation and determine which module (or modules) would cause the problem at hand. In most cases, the problem will involve only one board, and substituting a board known to be in good operating condition will easily isolate the problem. Locating problems on the filter modules may require removing these boards from the chassis by removing the bandswitch shaft and unsoldering the harness connections.

Once the problem has been isolated, refer to the appropriate portion of Section 2 for a full scale description of the circuit.

### 1-3. GENERALIZED THEORY OF OPERATION

The following discussion covers the theory of operation of the TR-7 in a general manner. Detailed circuit descriptions are found in Section 2 of this manual. Refer to figure 1-1 (TR-7 Block Diagram) and figure 1-2 (TR-7 Module Locations) for aid in following this discussion. The discussion is divided into three sections (receiver, transmitter and frequency control) for clarity.

#### 1-3.1 RECEIVER SECTION

Incoming signals from the antenna pass through a bandswitched low-pass filter module, the transmit/receive antenna switching, and a bandswitched high-pass filter module. These filters create an input bandpass filter, the limits of which are defined by the yellow numerals on the front panel BAND switch. A separate receiver and/or receive antenna can be connected in this path by removing the jumper between the EXT RCVR and EXT ANT jacks on the rear panel and making the appropriate connections.

The output of the high-pass filter is connected to the input of the Up-Converter module, along with the VLF antenna input and the 25 kHz calibrator output. The VLF antenna is connected through a 20 dB attenuator due to the fact that the input antenna filters are bypassed by this input. Signals at the input of the Up-Converter module are mixed with the output of the synthesizer VCO to create a 48.05 MHz intermediate frequency (IF) signal. Conversion is accomplished by a high-level, double balanced mixer to provide a very wide dynamic range. The output of this mixer is amplified by a low-noise, high dynamic range junction FET amplifier to insure adequate receiver sensitivity. This stage is followed by a four-pole monolithic 48.05 MHz crystal filter. The purpose of this filter is to attenuate signals removed more than  $\pm 4$  kHz from 48.05 MHz, thus protecting the remaining stages of the receiver from strong interfering signals. In this manner, optimum receiver dynamic range is preserved while providing excellent sensitivity.

The output of the Up-Converter module is routed to the input of the 2nd mixer module. This module provides additional gain at the 48.05 MHz 1st IF frequency and converts this signal to the 5.645 MHz 2nd IF frequency. Automatic gain control (AGC) voltage is applied to the 1st IF amplifier to supplement the control range supplied by later stages.

The 5.645 MHz signal from the 2nd mixer module is routed through the Noise Blanker module to the IF Selectivity module. When installed, the accessory NB-7 Noise Blanker acts on noise pulses prior to the IF crystal filters to prevent ringing in these filters from stretching the pulses. Maximum noise blanker effectiveness is thus assured. If the accessory NB-7 is not installed, the 2nd IF signal is passed through a jumper board in the same location for interconnection.

The IF Selectivity module contains provisions for 3 accessory crystal filters in addition to the standard 2.3 kHz filter. These filters determine the overall bandwidth of the receiver, and are selected by PIN diode switching controlled from the transceiver front panel. Careful attention has been given to the switching circuit design and physical layout of this module to minimize stray coupling paths which would degrade the ultimate selectivity of the receiver. The result is extremely high rejection of unwanted off-channel signals.

Following the IF Selectivity module, the 5.645 MHz signal is routed to the 2nd IF module. This module amplifies the 5.645 MHz signal and demodulates it using an AM or product detector, depending on mode. The demodulated signal is then amplified to a level sufficient to drive a speaker by an integrated circuit audio amplifier. AGC voltage, developed prior to demodulation, is used to control the gain of the IF stages. The same AGC signal is used to drive the S-meter circuit to provide signal strength indication. AGC decay time constants are selected by the MODE switch and front panel F/S switch.

### 1-3.2 TRANSMITTER SECTION

In the transmit mode, audio signals from the MIC jack are applied to the Transmit Exciter module, where they are amplified and used to drive the balanced modulator and VOX circuits. The VOX section automatically controls the transmit/receive switching in the AM and SSB modes. A push-to-talk (PTT) input is also provided for manual control.

The 5.645 MHz double sideband output of the balanced modulator is routed through the Noise Blanker module to the IF Selectivity module. The signal is passed straight through the noise blanker for interconnection purposes only. The IF selectivity module rejects the undesired sideband, using the 2.3 kHz crystal filter. This is accomplished by correct positioning of the double sideband signal relative to the crystal filter.

The 5.645 MHz single sideband signal from the IF

Selectivity module is connected to a summing amplifier on the 2nd IF module. In the SSB and RTTY modes, the signal is passed through to a variable attenuator. In the AM mode, the signal is summed with the BFO signal to create an AM signal before being passed to the variable attenuator. In the CW mode the balanced modulator is disabled, and a 5.645 MHz crystal oscillator is keyed to create an offset CW signal for application to the variable attenuator.

The variable attenuator consists of a PIN diode which is controlled by the ALC circuitry. The outputs of the forward and reflected wattmeter and the CARRIER control are connected to the ALC module. These signals are summed to create a controlling signal for the attenuator, thus controlling the transmitter drive level. VSWR protection is accomplished in this manner, as well as providing gain control to prevent flat topping and overdrive.

The 5.645 MHz transmit IF signal developed in the 2nd IF module is connected to the 2nd mixer module. The signal is converted to 48.05 MHz and amplified, then routed to the Up-Converter module.

In the Up-Converter module, the transmit signal is filtered by the 4-pole 48.05 MHz crystal filter to remove any spurious content, amplified, and converted to the operating frequency by mixing it with the output of the synthesizer VCO.

The output of the Up-Converter module is filtered by the high-pass filter module, and routed through the transmit/receive switching to the Power Amplifier module, where it is amplified to the final output level. The signal is then routed by the transmit/receive switching to the low-pass filter module to attenuate the harmonics developed in the power amplifier. The transmit signal then passes through the wattmeter to the antenna jack.

### 1-3.3 FREQUENCY CONTROL

The TR-7 features synthesizer control of the operating frequency. This allows the transceiver to cover a wide frequency range without the use of range crystals or other frequency determining circuits.

The reference for the synthesizer is generated by a 40 MHz crystal oscillator on the PBT/Reference Oscillator module. The output of this oscillator is divided by 80 to produce 500 kHz. These two signals (40 MHz and 500 kHz) are routed to the synthesizer modules, which are described later in this section.

When the CAL switch is depressed, the 500 kHz signal is divided by 20 to produce a 25 kHz signal which is rich in harmonics. This signal is connected to the input of the Up-Converter module, and produces calibration marker signals at 25 kHz intervals.

The passband tuning controls are connected to a 13.695 MHz voltage-controlled crystal oscillator (VCXO) through a switching circuit. Control of this oscillator is thus switched between the front panel PBT control and the internal controls which are selected by the MODE switch. Although this oscillator is crystal controlled, it is designed to allow the frequency to be moved over a limited range (approximately  $\pm 3$  kHz) centered on 13.695 MHz. This signal is then mixed with the 40 MHz crystal oscillator signal to produce 53.695 MHz and with an 8.05 MHz crystal oscillator to produce 5.645 MHz.

The 53.695 MHz signal is used for injection to the 2nd mixer module, where it converts the 48.05 MHz IF signal to 5.645 MHz. The 5.645 MHz signal is used as a BFO signal for the generation and demodulation of SSB, CW, and RTTY signals. Since the 13.695 MHz oscillator is used to generate both signals, it can be moved in frequency without changing the receiver operating frequency. Therefore, as the BFO frequency is changed (by changing the PBT control voltage), the 53.695 MHz injection signal is changed by an equal amount. This allows the 2nd IF to be positioned anywhere within a  $\pm 3$  kHz range with respect to the crystal filter passband while the receiver remains tuned to the incoming signal. This technique provides the passband tuning feature in addition to sideband selection.

Injection for the Up-Converter module is supplied by the VCO module. This module includes a voltage-controlled oscillator (VCO) which operates over the range of 48.05 MHz to 78.05 MHz. When mixed with the 0.30 MHz incoming signals, the result is the 48.05 MHz IF frequency. The VCO is tuned by a filtered control voltage derived from a phase detector which compares the frequency and phase of the 500 kHz reference from the PBT/Reference Oscillator module and a 500 kHz signal from the Translator module.

The Translator module combines the 40 MHz reference signal and the 5.05-5.55 MHz output of the permeability-tuned oscillator (PTO) which is controlled by the main tuning dial. The resulting 45.05-45.55 MHz signal is filtered and mixed with the VCO signal to produce a 3.0-33.0 MHz signal,

depending on operating frequency. This signal is filtered, amplified, and applied to a programmable divider ( $\div N$ ) which is programmed by the Digital Control module. The output of the  $\div N$  is exactly 500 kHz when the VCO is tuned to the correct frequency, thus satisfying the phase detector and locking the synthesizer loop.

The Digital Control module generates programming information for the  $\div N$  by processing information from both the BAND switch and the frequency programmer on the DR-7 display module. The BAND switch information generates the proper  $\div N$  load number for the frequency range indicated by the white bandswitch numerals. The DR-7 frequency programmer is then used to increment this load number UP or DOWN by the desired amount.

The following example will help to illustrate the operation of the synthesizer:

Operating Frequency:	<u>14.2835 MHz</u>
	+48.0500 MHz
VCO Frequency:	62.3335 MHz
PTO Frequency:	
5.05 MHz + 0.2835 MHz =	5.3335 MHz
	+40.0000 MHz
Variable Reference Frequency:	45.3335 MHz
$\div N$ Input Frequency:	
62.3335 MHz - 45.3335 MHz =	17 MHz
$\div N$ Output:	.5 MHz
	(Load number = 34)

It can be seen from the above that each time the  $\div N$  load number is increased or decreased by one, the VCO frequency will be forced to change by 500 kHz to satisfy the phase detector and maintain a locked condition. By the same token, as the PTO is tuned, the VCO must follow exactly to maintain phase lock.

The DR-7 Frequency Display module contains a counter with a six digit LED readout. In the normal mode, this counter is connected to the VCO output and is programmed to subtract 48.05 MHz from the resulting count. In this manner, operating frequency is displayed on the LED readout. In the external mode, the 48.05 MHz subtraction is removed, and the counter input is connected to the rear panel counter input jack, resulting in a 150 MHz six digit counter for test purposes.

#### 1-4. SPECIAL TOOLS AND FIXTURES

A special set of tools and fixtures is available for servicing the TR-7. This set includes all unique board extenders, a Jumper Board, and alignment tools needed to troubleshoot and align the transceiver. This kit is available from the R.L. Drake Company for a nominal fee.

##### 1-4.1 BOARD EXTENDERS

In order to extend a circuit card out of the card cage for servicing, refer to figure 1-3 and select the proper board extenders from the table. Remove the circuit card to be tested, install the board extenders so that

each pin of each circuit card connector is extended, and reinstall the circuit card on the extenders. To service a card located underneath the DR-7 remove the DR-7 and replace it with the Jumper Board included in the service kit.

##### NOTE

Performance of the TR-7 will be degraded when some cards are extended. After replacing a faulty component or otherwise correcting a problem, the transceiver should be realigned in accordance with Section 3 with all boards in place in the card cage.

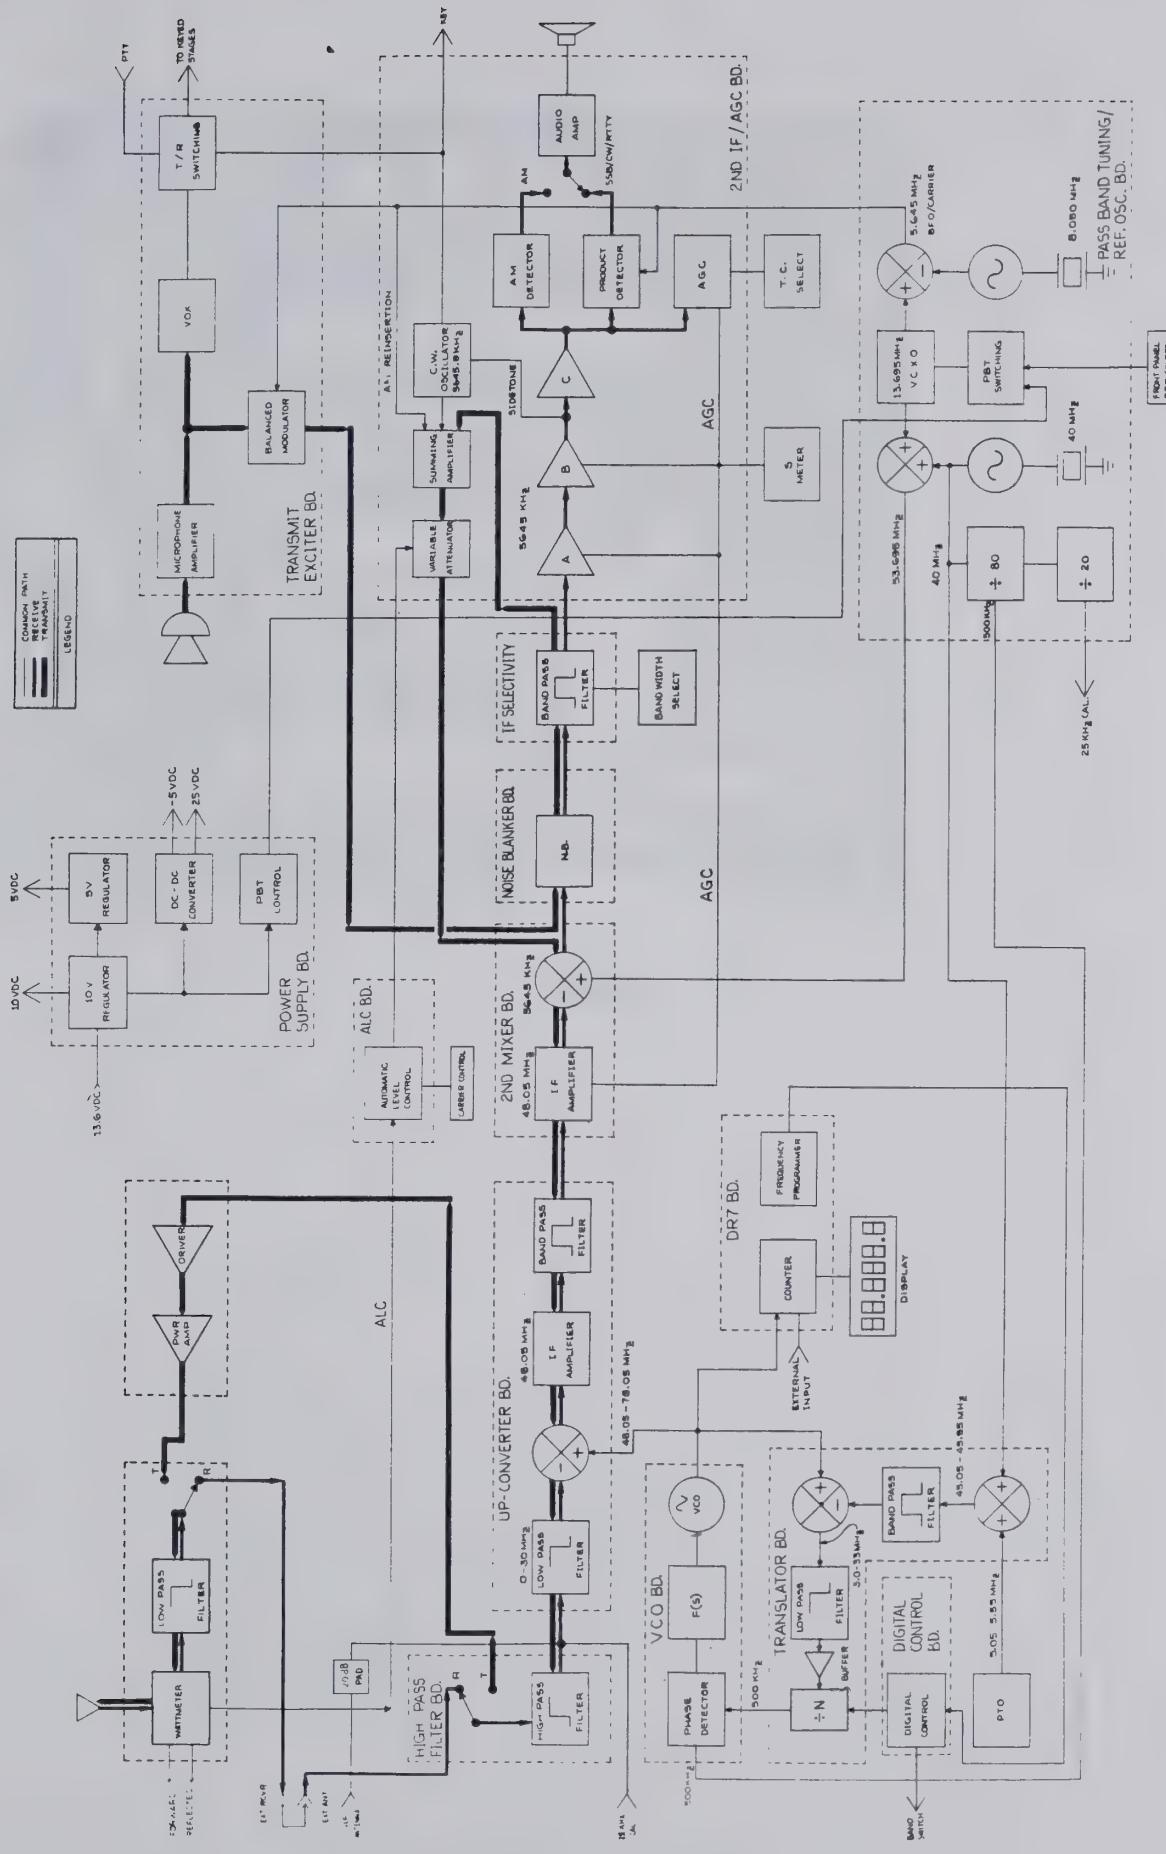

CIRCUIT CARD	EXTENDER TYPE & NUMBER REQUIRED				
	3 PIN	4 PIN	5 PIN	6 PIN	9 PIN
Digital Control (See Note 1)		1	1	1	1
Transmit Exciter (See Note 2)	1	2	1	1	
Up Converter	2				
VCO (See Note 2)	1	1			1
Translator (See Note 3)	2				1
2nd Mixer	2	1			
IF Switching or Noise Blanker		1		1	
IF Selectivity	3				
PBT/Reference	1	1		1	2
2nd IF/Audio		1	1	4	
Power Supply (See Note 4)				2	
ACCESSORIES					
DR-7	2			2	1
AUX-7		2		1	1

##### NOTES:

1. Use a 9 pin extender on Translator end of Jumper Board.
2. Extend Jumper Board with (2) 6 pin and (1) 9 pin extenders.
3. Use (2) 6 pin extenders on Digital Control end of Jumper Bd.
4. Limit operating time to 15 minutes due to lack of heat sink.

## SECTION 2

### CIRCUIT DESCRIPTION

The following sections describe the circuit of each of the modules and/or circuit cards in detail. Each section contains a schematic diagram, parts location overlay, and parts list. When ordering replacement parts, please refer to the R. L. Drake Company part number listed for the part in question.

#### 2-1. PARENT BOARD/CHASSIS

The Parent Board and Chassis (Wiring Harness) combine to interconnect the various circuit cards and modules in the TR-7. Refer to figure 2-2 for schematic and figure 2-1 for parts location information. Figure 2-1 also identifies the major interconnection circuits on the Parent Board as an aid for troubleshooting and alignment.

Each circuit board/module has been assigned an identifying number for circuit description and parts identification purposes in accordance with the following list:

Identification Prefix	Circuit Board/Module
01	Auxiliary Program (Accessory)
02	Digital Control
03	Transmit Exciter
04	Up-Converter
05	VCO
06	Translator
07	2nd Mixer
08	IF Switching or Noise Blanker (Accessory)
09	IF Selectivity
10	Pass Band Tuning/Reference
11	2nd IF/Audio
12	Jumper
13	High Pass Filter
14	High Pass Filter Switch, Front
15	High Pass Filter Switch, Rear
16	ALC
17	Low Pass Filter, Bands 1-4
18	Low Pass Filter, Bands 5-8
19	Low Pass Filter Switch, Front
20	Low Pass Filter Switch, Rear
21	Power Supply/Regulator
22	Predriver
23	Power Amplifier
90	DR-7 (Accessory)

The identification prefix is used whenever referring to a particular circuit card. For example, the designator for resistor number 25 on the 2nd

IF/Audio Board is R1125. Pin 16 of the same card is numbered 11/16. Figures 2-1 and 2-2 include these identification prefixes for reference.

Refer to figure 1-1 to aid in following the signal flow through figure 2-2. Note that several power and/or control lines are identified by function. For example, the notation +10 CAL indicates that +10 VDC is present on this line when the calibrator is enabled. +10T AM indicates that +10 VDC is present in transmit in the AM mode. It is possible to isolate a large number of faults to the board level by making the necessary measurements on the Parent Board, utilizing figures 2-1 and 2-2 for location information.

The PTO switching circuitry selects the frequency controlling signal in the receive and transmit modes and applies this signal to pin 38 of the Translator module. Frequency control can be derived from one of four sources: the internal PTO, the RV-7, the R-7, or the crystal oscillator on the AUX-7 (for fixed frequency operation). PIN diodes CR9 through CR13 select the desired signal and couple it through C2 to the Translator Board. Since R22 is a common return resistor for all of the PIN diode switches, back bias is automatically applied to the unused signal paths. The Spot function is obtained by enabling two signal paths at once. CR16 and CR17 form a detector to provide an audio indication of zero beat. Q1, Q2 and Q3 control the RV-7/TR-7 selection in receive, and Q4, Q5 and Q6 perform the same function in transmit. Selection of the R-7 PTO is accomplished via the RCT switch (S5E) and circuitry in the R-7. The fixed oscillator is selected by the Fixed switches (S4D and S4E) via CR14, CR15 and circuitry on the AUX-7.

The RIT function is controlled by U1, which switches the RIT control line between the front panel RIT control (R10B) and the internal RIT centering control (R24). When the RIT function is not selected, the RIT line is controlled by R24 in both receive and transmit.

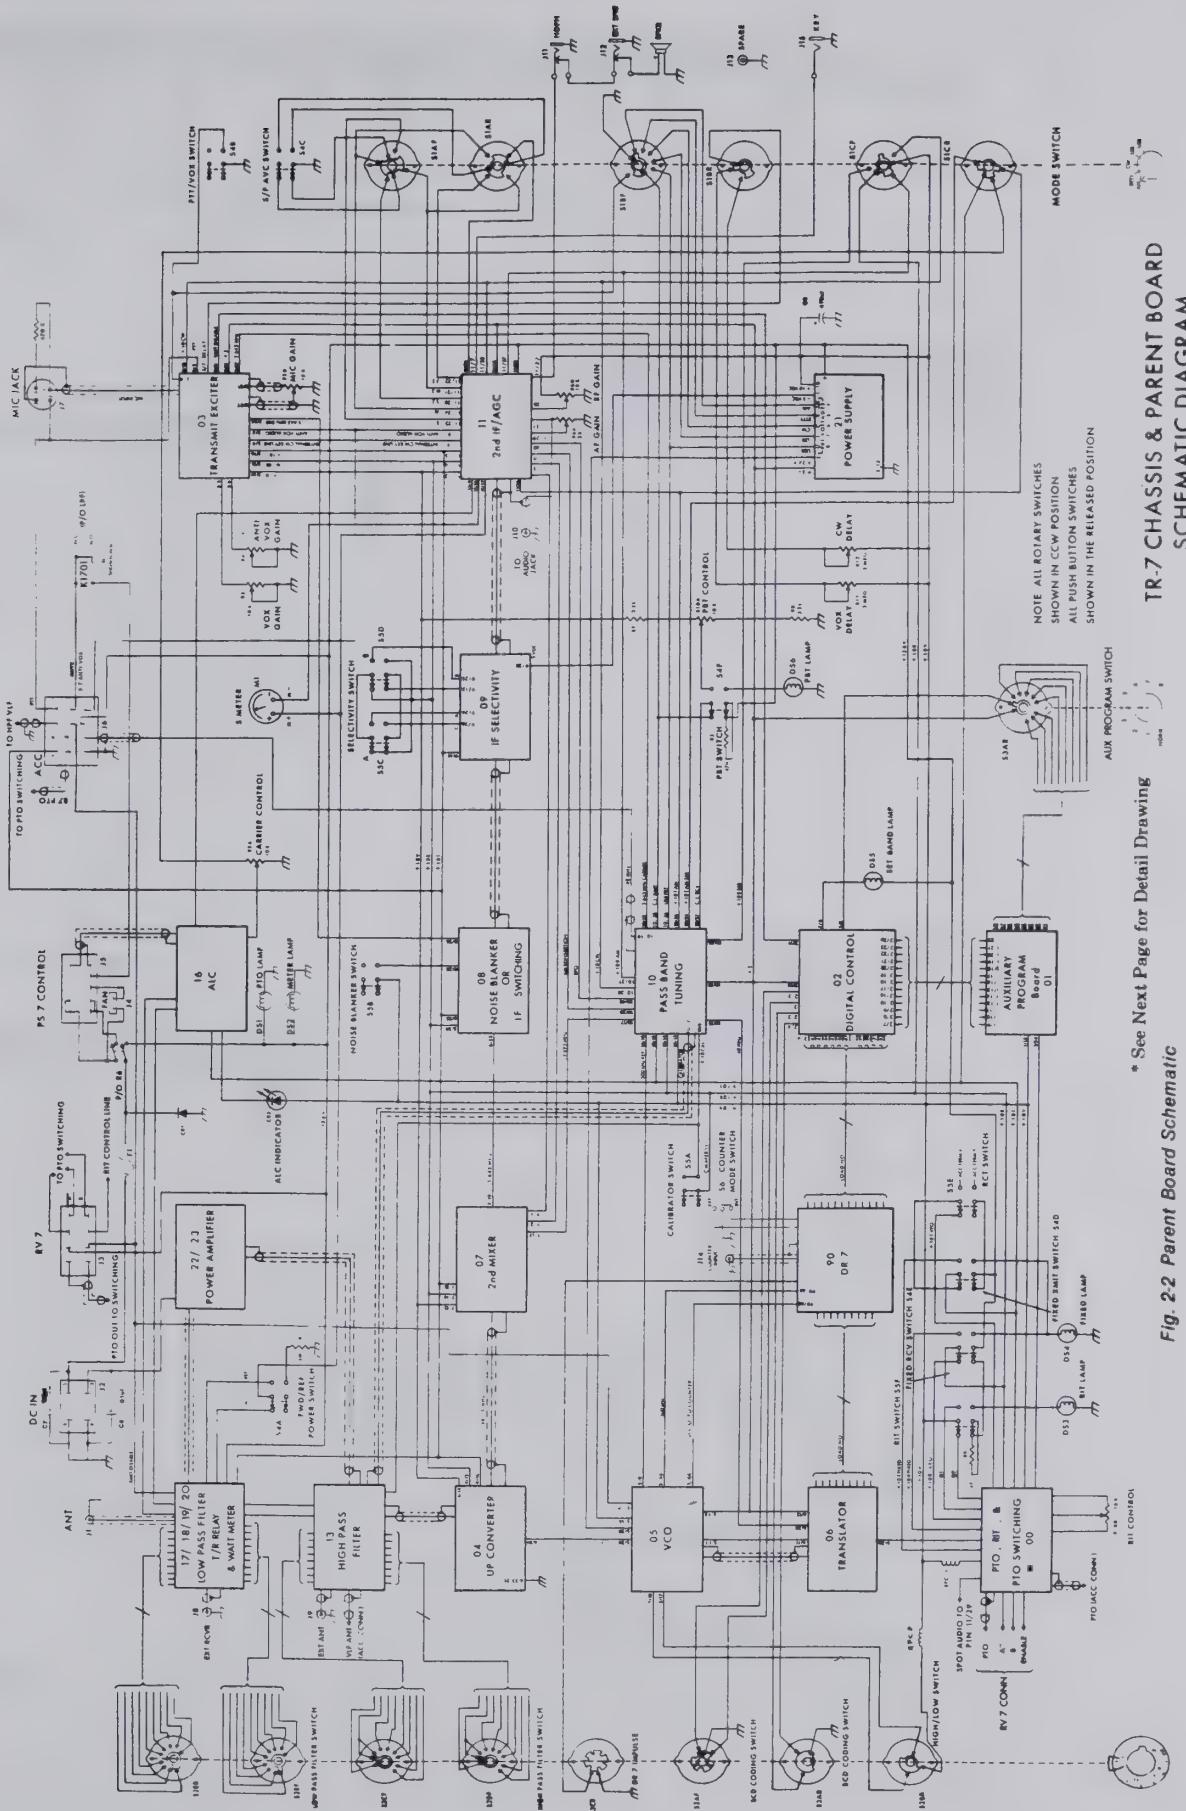

Fig. 2-2 Parent Board Schematic

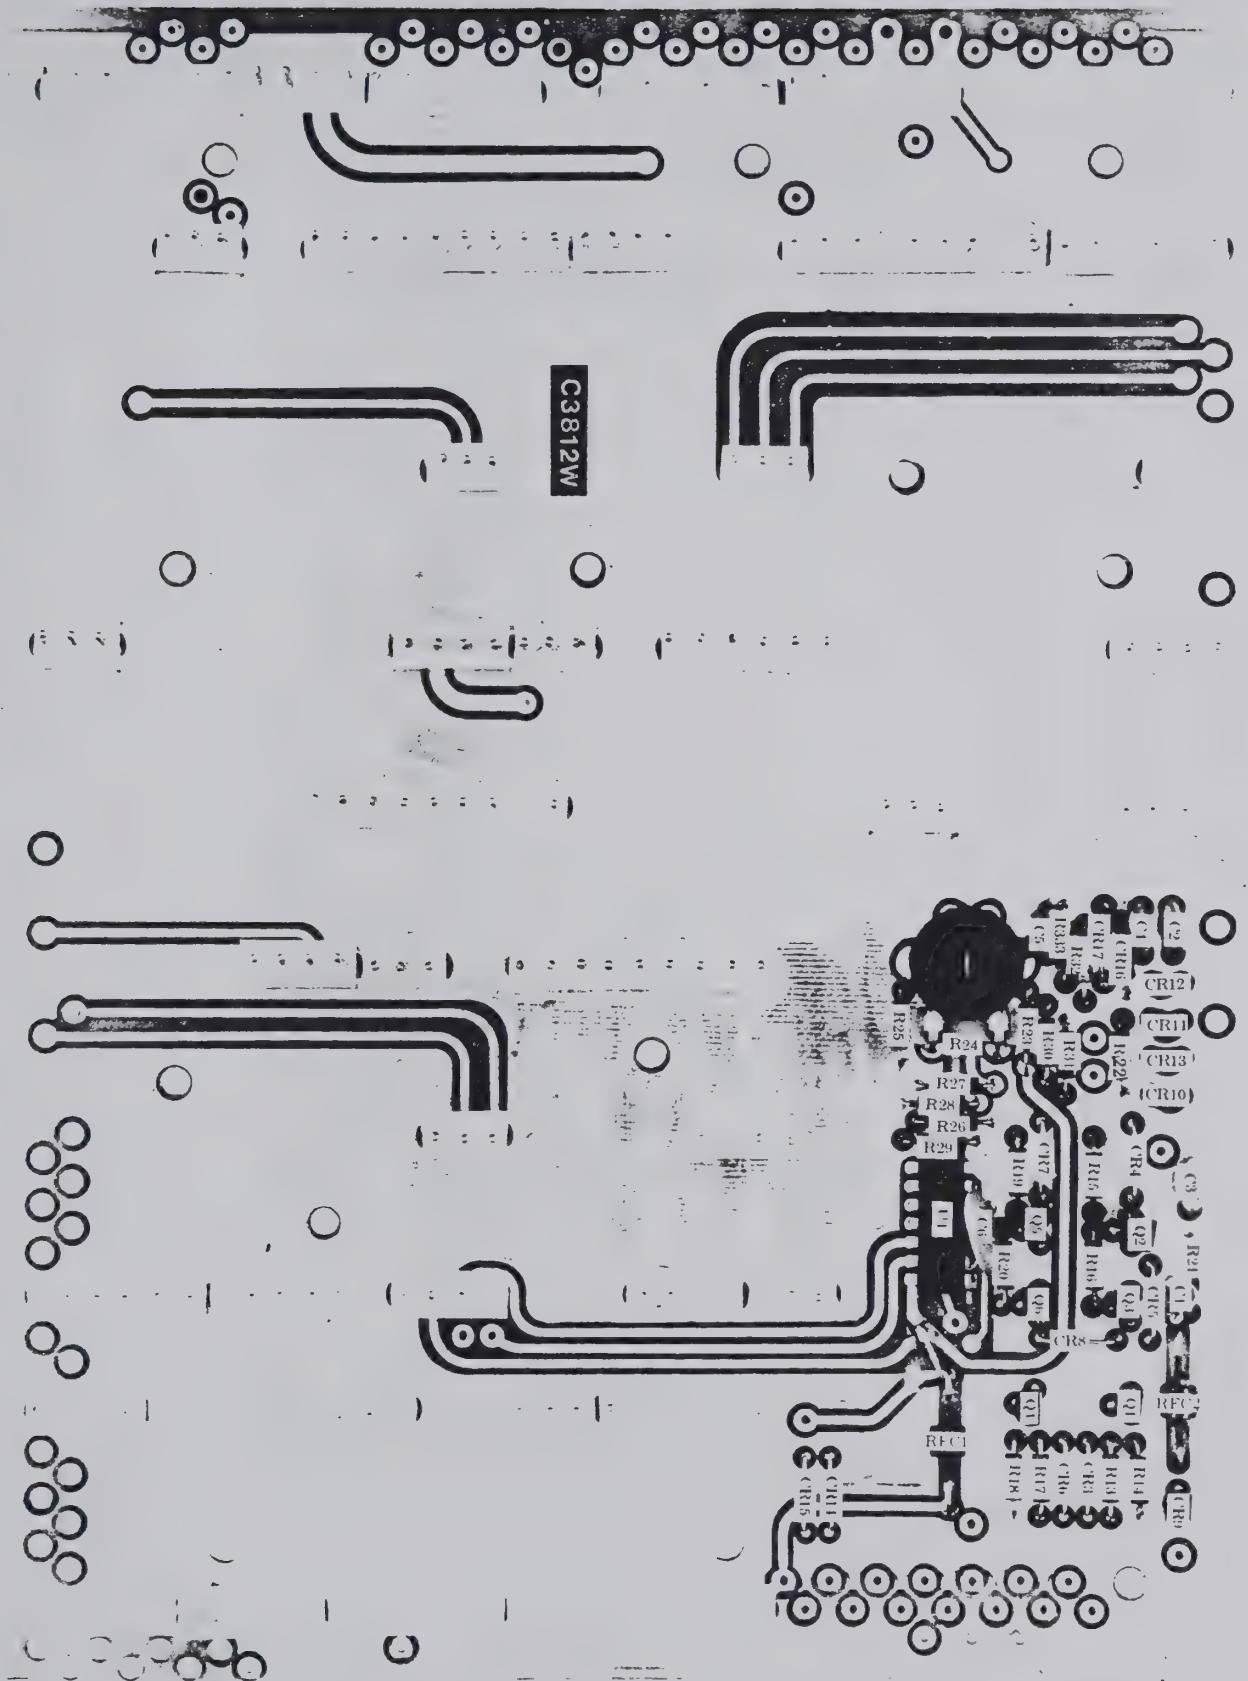

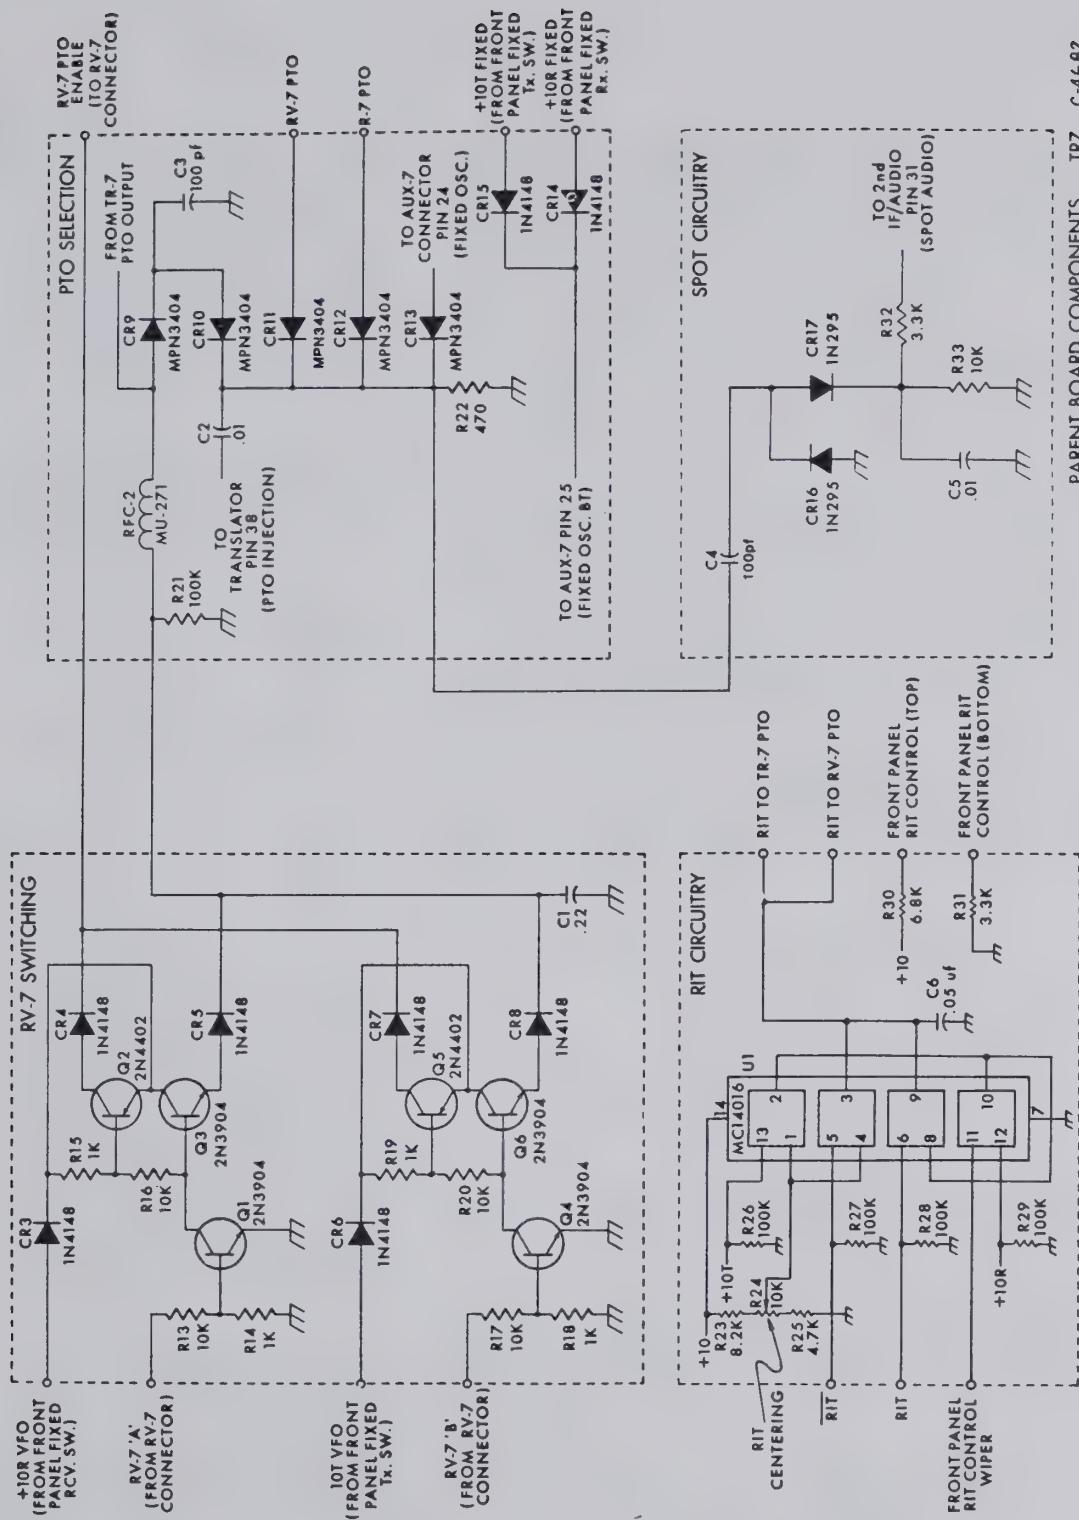

Fig. 2-1 Parent Board Pictorial

PARENT BOARD COMPONENTS TR7 C-4682

## 2-2. DIGITAL CONTROL BOARD

The Digital Control Board decodes the BCD bandswitch information to provide frequency range programming and band control. In addition, it selects between normal and auxiliary frequency range programming and provides transmitter lockout on unauthorized frequencies. Refer to figure 2-4 for schematic and figure 2-3 for parts location information.

BCD band information from the HPF module rear switch board is connected to Digital Control Board pins 1 through 4 via the Parent Board. This information is coded as follows (L=Low, H=High):

BAND PIN 1 PIN 2 PIN 3 PIN 4 DECIMAL CODE

1.5	L	H	L	L	2
2.5	H	H	L	L	3
3.5	L	L	H	L	4
5.0	H	L	H	L	5
7.0	L	H	H	L	6
14.0	H	H	H	L	7
21.0	L	L	L	H	8
28.5	H	L	L	H	9

This data is connected to the BCD input of a BCD-to-decimal decoder, U201, which converts the data to a one out of ten (decimal) code. The band coding is further processed by quad OR gates U203, U204 and U205 to create the correct synthesizer range programming numbers corresponding to the white numbers on the band switch. This information is connected to the X inputs of 4-bit selectors U206 and U207. Range information from the AUX-7 module is connected to the Y inputs of 4-bit selectors U206 and U207.

When the front panel AUX PROGRAM switch is in the NORM position, 5 volts is applied to module pin 5. This signal is connected to the A control inputs of U206 and U207 allowing the data on the X inputs (from the bandswitch) to program the synthesizer range via the Jumper Board or DR-7. The Y inputs are inhibited in this mode.

When one of the eight AUX PROGRAM channels is selected, module pin 5 is disconnected from 5 volts, and pulled low by R219. This signal is inverted by U209, and a high output appears on U209 pin 3, which is connected to the B control inputs of U206 and U207. This allows the Y inputs (from the AUX-7) to program the synthesizer range.

BCD band information from the bandswitch is compared to BCD band information from the AUX-7 in comparator U202. When the two sets of data are equal, pin 3 of U202 goes high, which causes the output of the NOR gate in U209 (pin 5) to go low. This turns off transistor Q202, causing the SET BAND light to extinguish. In the NORM mode, pin 6 of U209 is held in the high state, forcing the output of the NOR gate to stay low at all times, thus causing the SET BAND light to remain off.

The transmit function of the TR-7 is enabled whenever pin 11 of the Digital Control Module is high (ungrounded). This means that Q201 must be off, which is accomplished by keeping U209, pin 11 in the low state. Pin 11 of U209 will be low when pins 12 and 13 are high, and this condition will exist if pin 14 or pin 15 of U209 is low. Pin 14 enables the transmitter in the NORM mode, and pin 15 enables the transmitter in the AUX mode.

In the NORM mode, pin 14 of U209 will be low if pin 1 of U208 is low, which will be true if all four inputs of the four input NAND gate are high in accordance with the following table:

U208 PIN NO.	CONDITION FOR HIGH STATE
2	Not on 2.5 or 5.0 MHz bands
3	Legitimate Amateur Band (from DR-7)
4	Normal Mode Selected
5	Synthesizer Locked

If all conditions in the above table are satisfied, the transmitter will operate in the NORM mode.

Similarly, in the AUX mode, pin 13 of U208 must be low, which will be true if all four inputs of the NAND gate are high in accordance with the following table:

U208 PIN NO.	CONDITION FOR HIGH STATE
9	Synthesizer Locked
10	AUX Mode Selected
11	BAND Setting Correct
12	RTM-7 Installed

If all these conditions are as listed, the transmitter will operate in the AUX mode.

The Digital Control Board does not require alignment.

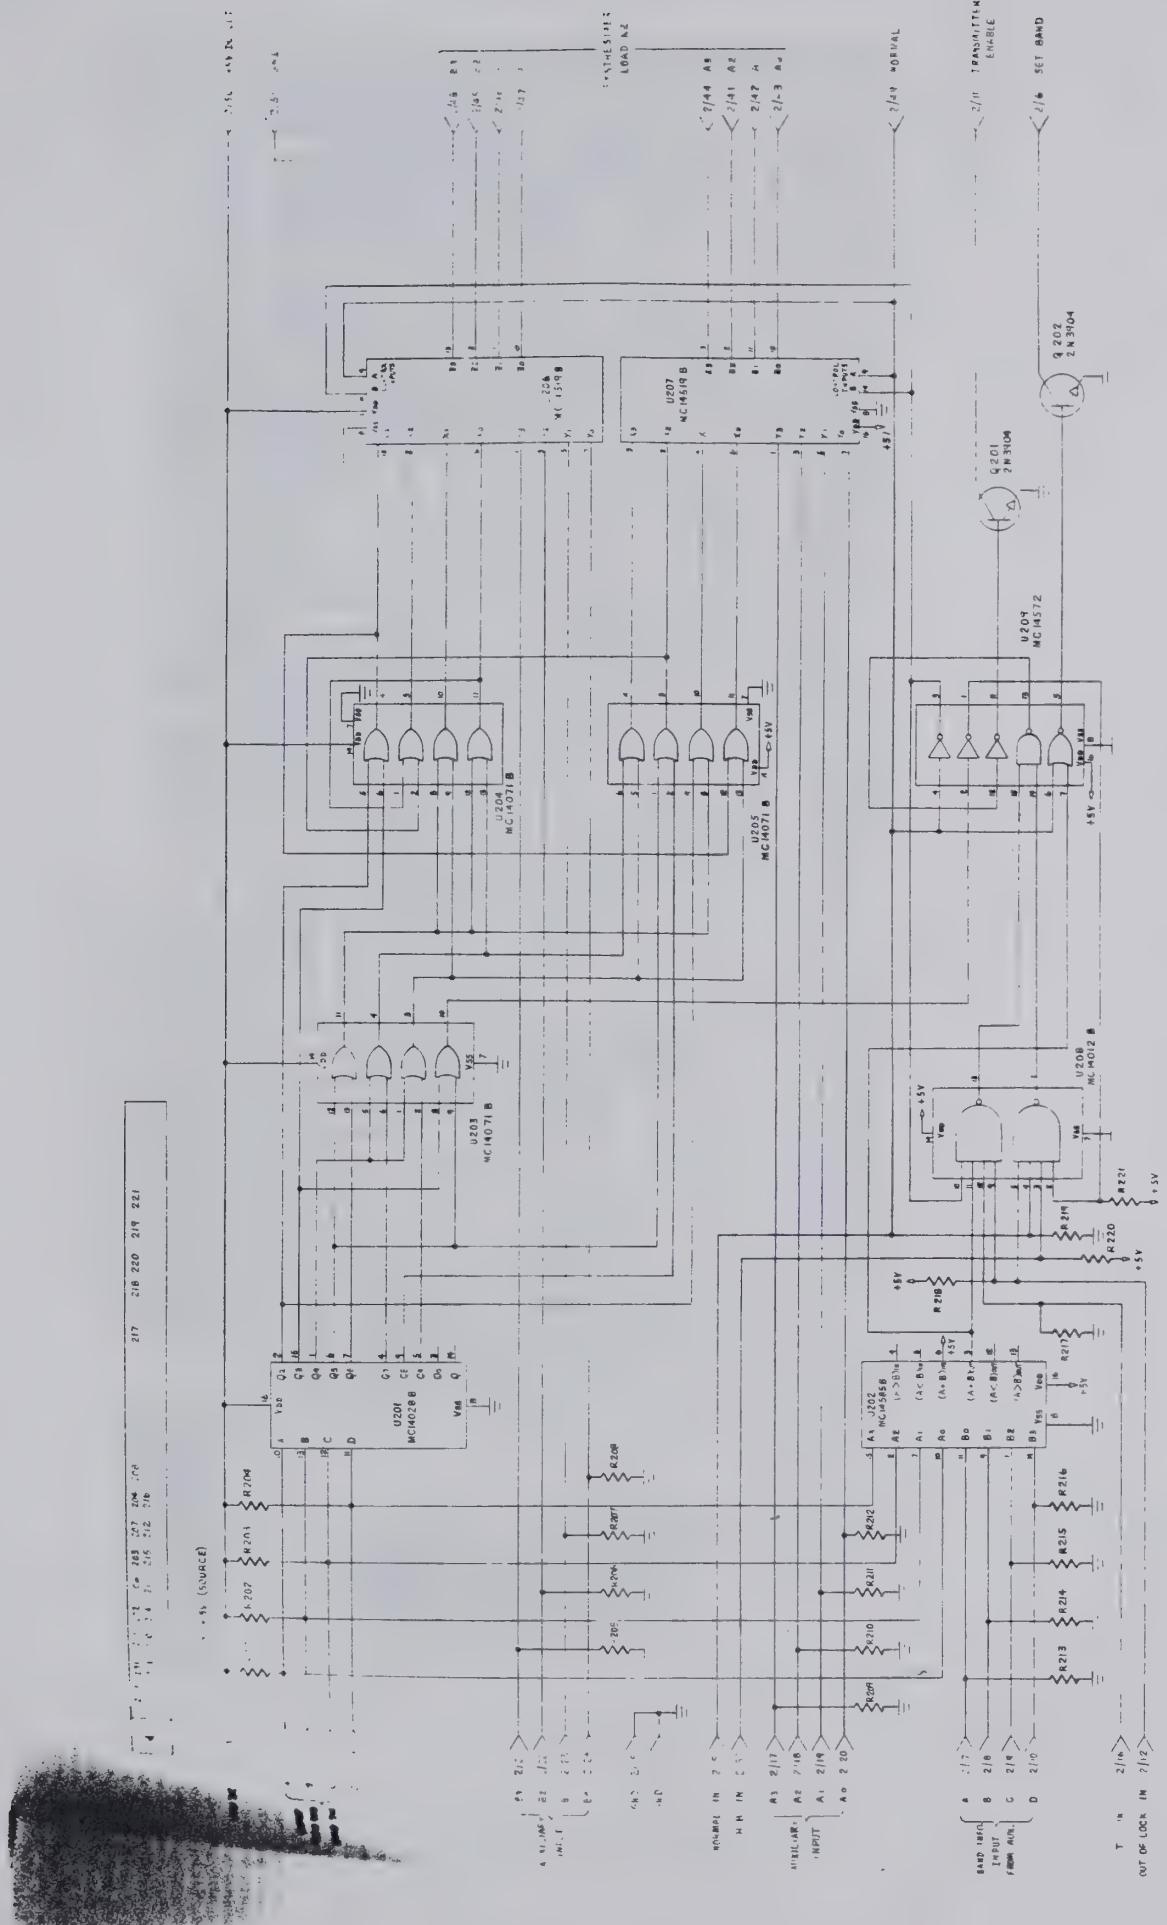

Fig. 2-4 Digital Control Board Schematic

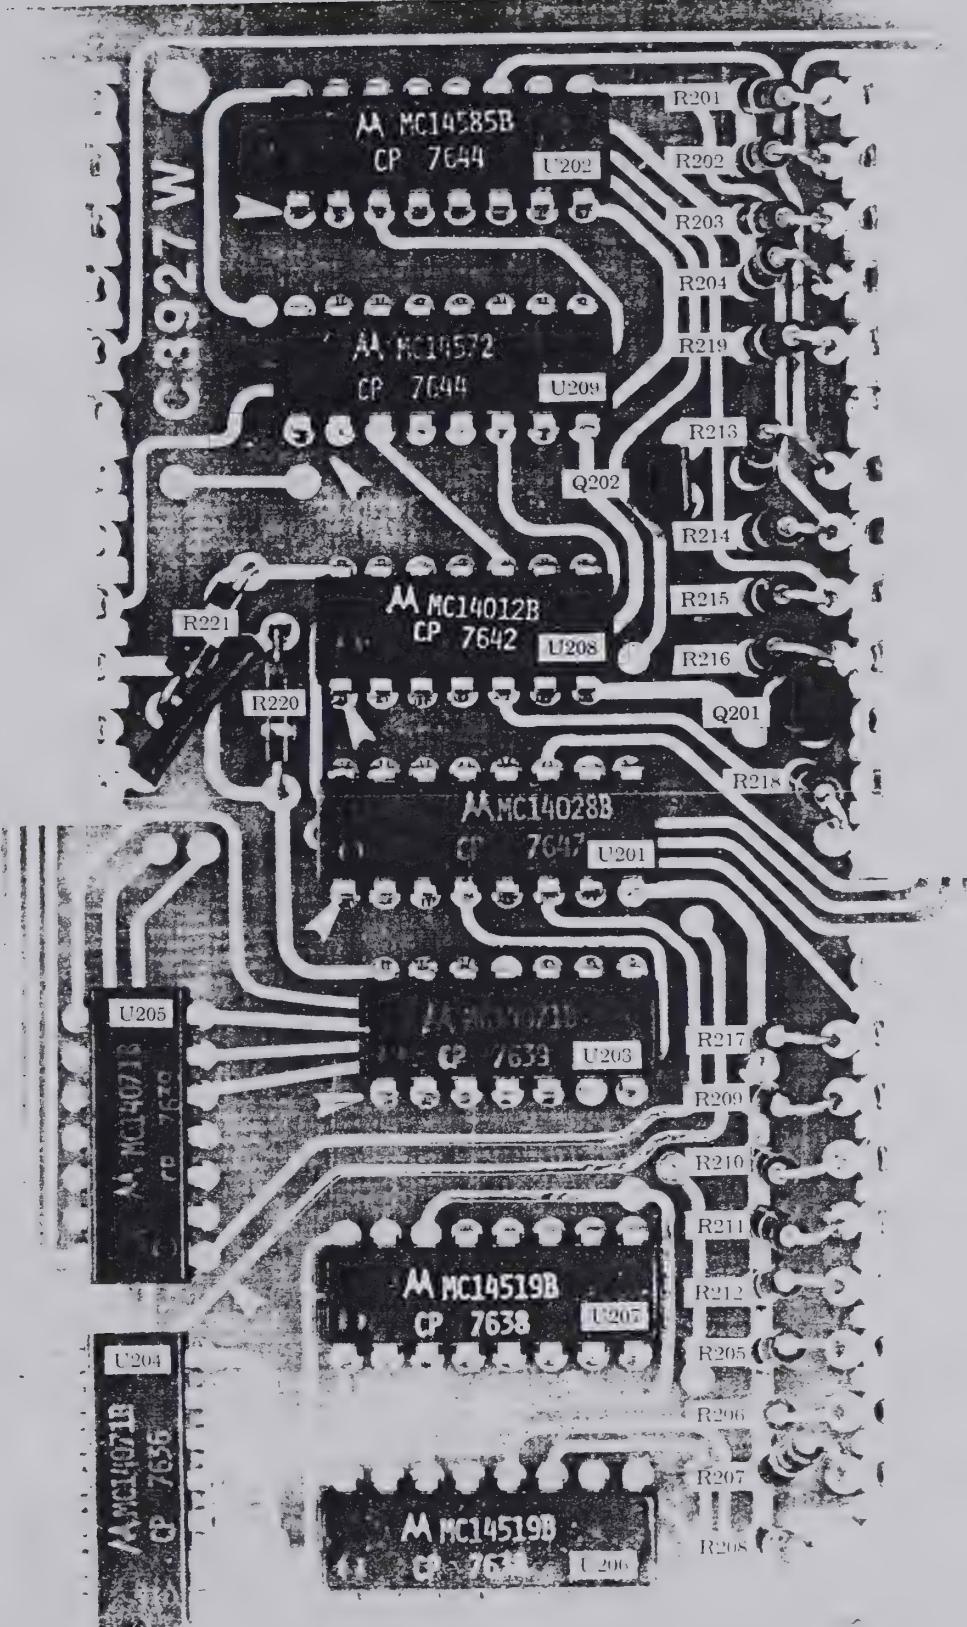

Fig. 2-3 Digital Control Board Pictorial

### 2-3. TRANSMIT EXCITER BOARD

The Transmit Exciter Board amplifies the speech audio from the microphone, provides VOX and anti-VOX circuitry, and includes the 10 volt transmit/receive switching. In addition, this module also contains the transmitter balanced modulator. Refer to figure 2-6 for schematic and figure 2-5 for parts location information.

Microphone audio from the front panel connector is applied to pin 1 of the Transmit Exciter via the Parent Board. This signal is amplified by Q301, Q302 and associated components, and is coupled to pin 21 for connection to the top of the front panel MIC GAIN control. Provisions have been made on the board to jumper the free end of R356 to ground for low impedance microphone input, if required. This jumper is not installed at the factory, and is, in fact, seldom required for proper operation.

The wiper of the front panel MIC GAIN control is connected to pin 22, and coupled to an emitter follower consisting of Q304 and associated components. The output of this stage is coupled to pin 1 of the MC-1496P balanced modulator. The 5.645 MHz carrier signal is coupled to pin 10 of the MC-1496P via a diode switch consisting of CR307 and CR308. In transmit, 10 volts is applied to the anodes of these diodes via R351, causing current to flow via R352 and L301, thus allowing the 5.645 MHz carrier signal to pass. In receive, the diodes are turned off, disabling the balanced modulator. Control R349 is the carrier balance adjustment.

The output of the balanced modulator is taken from pin 6 of the MC-1496P and coupled to a buffer stage consisting of Q309 and associated components. This stage is active only in transmit, thus assuring proper transmitter muting in the receive mode. The double sideband (DSB) signal is then coupled to pin 24 of the Transmit Exciter for routing to the IF Selectivity Board for sideband selection.

Microphone audio from Q302 is also coupled to VOX buffer Q303, and detected by CR305 and CR306. The resulting dc voltage is amplified by U301A, the gain of which is set by the front panel VOX GAIN control connected between module pin 5 and ground. VOX operation is enabled via the VOX override line, pin 4. When this pin is grounded, the output of U301A is shorted, disabling the VOX.

Anti-VOX audio from the speaker is connected via

pin 8 to a detector consisting of CR301 and CR302. The dc output of this detector is amplified by U301B, the gain of which is set by the front panel ANTI-VOX GAIN control and connected between module pin 6 and ground.

The VOX signal from U301A is applied to the inverting input of U301C and the ANTI-VOX signal is applied to the non-inverting input of U301C. These signals are compared, and when the VOX signal is greater, the output of U301C is forced low. In the CW mode, a keyed voltage is applied to the inverting input of U301C to achieve the same effect.

The output of U301C is connected to the inverting input of U301D. Thus, when the output of U301C is low, the output of U301D goes high, providing a keying signal. VOX delay is established by C303 and the front panel VOX DELAY control, which is connected between pin 7 and 10 volts. A separate delay control is brought into play on CW, via the MODE switch. R310 is used to establish a minimum delay to insure smooth transmit/receive switching.

The output of U301D is applied to pin 6 of U302. PTT information is applied to pin 1 of U302 via switching transistor Q305. When the transmit enable line (module pin 11) is high, the AND gates in U302 will drive the output switching transistors in this IC to the on state when either the VOX is tripped or the PTT line is grounded.

When either of the output drivers in U302 turn on, base current flows in Q306, thus enabling the 10 volt transmit line (+10T). At the same time, Q308 is turned off, turning off Q307 and disabling the 10 volt receive line (+10R). When the output drivers of U302 are off (caused by the absence of a VOX or PTT signal), exactly the opposite is true. In this manner, pin 15 (+10R) and pin 16 (+10T) are controlled for transmit/receive switching throughout the remainder of the radio. The network consisting of R362, C324, CR309 and CR310 provides a fast turnoff/delayed turn on signal to the base of Q308 to eliminate any possible critical sequencing problems in the T/R switching circuitry.

It should be noted that switches Q306 and Q307 do not have any current limiting protection, since +10R and +10T must be well regulated. As a result, if a short is developed within the radio on either the +10R or +10T lines, the accompanying switching transistor will probably be destroyed. Care should be taken to avoid such shorts when servicing the TR-7.

## 2-4. UP-CONVERTER BOARD

The Up-Converter Board converts incoming received signals to the 1st IF of 48.05 MHz, and converts the transmit 48.05 MHz IF signal to the desired signal frequency, using the output of the synthesizer VCO. Refer to figure 2-8 for schematic and figure 2-7 for parts list information.

- Received signals from the antenna are routed to the Up-Converter via the low pass and high pass filter modules. These signals first pass through a master low pass filter consisting of C407-C413 and L402-L404. This filter is employed to improve image and spurious response performance, and has a cut-off frequency of approximately 35 MHz. The output of this filter is connected to the signal input of a high-level double balanced mixer, which is a packaged, diode-ring device. The injection input of this mixer is driven by an amplifier, Q401, whose input is the output of the synthesizer VCO. Q401 is a broadband amplifier, with a flat passband over the 48-78 MHz injection range. R406, R407 and R408 form a pad to insure proper termination of both the amplifier and the mixer.

The 48.05 MHz difference signal is coupled from the IF port of the mixer to the source of IF amplifier Q402 through pin diode CR401, which is turned on by +10R through RFC402. Since CR403 shares a common dc return through R413, it is biased off. C418 and T402 tune the output of Q402, and this signal is coupled to the 48.05 MHz filter through CR404, which is turned on by +10R through RFC406. Since CR402 shares a common dc return through R414, it is biased off.

The 48.05 MHz filter module consists of two monolithic filter elements, each of which is a two-pole filter. Matching is accomplished by C421, C422, and L405 on one end, and C423, C424 and L406 on the other end. L405 and L406 are tuned at the factory using sophisticated equipment, and should not require readjustment unless a filter element is replaced. Nominal bandwidth of this filter is 8-12 kHz.

In transmit, the signal flow is reversed. The 48.05 MHz transmit IF signal is passed through the crystal filter and amplified by Q402. In this case, CR402 and CR403 are turned on by +10T, and CR401 and CR404 are biased off. The output of Q402 is thus connected to the double balanced mixer, which is bilateral, and does not require T/R switching. The 48.05 MHz signal is mixed with the synthesizer injection to create a signal on the desired transmit frequency. This signal is passed through the master low pass filter and routed to the input of the Power Amplifier via the High Pass Filter module.

Due to the high frequencies involved, proper grounding is very important on this module. If any shields are removed for servicing, be sure that they are replaced and soldered as originally produced. In addition, be sure that all four grounding clips are properly installed. These clips may be soldered to the shield if necessary. Proper attention to these details will insure that spurious responses are minimized.

Alignment of this module is covered in Section 3.

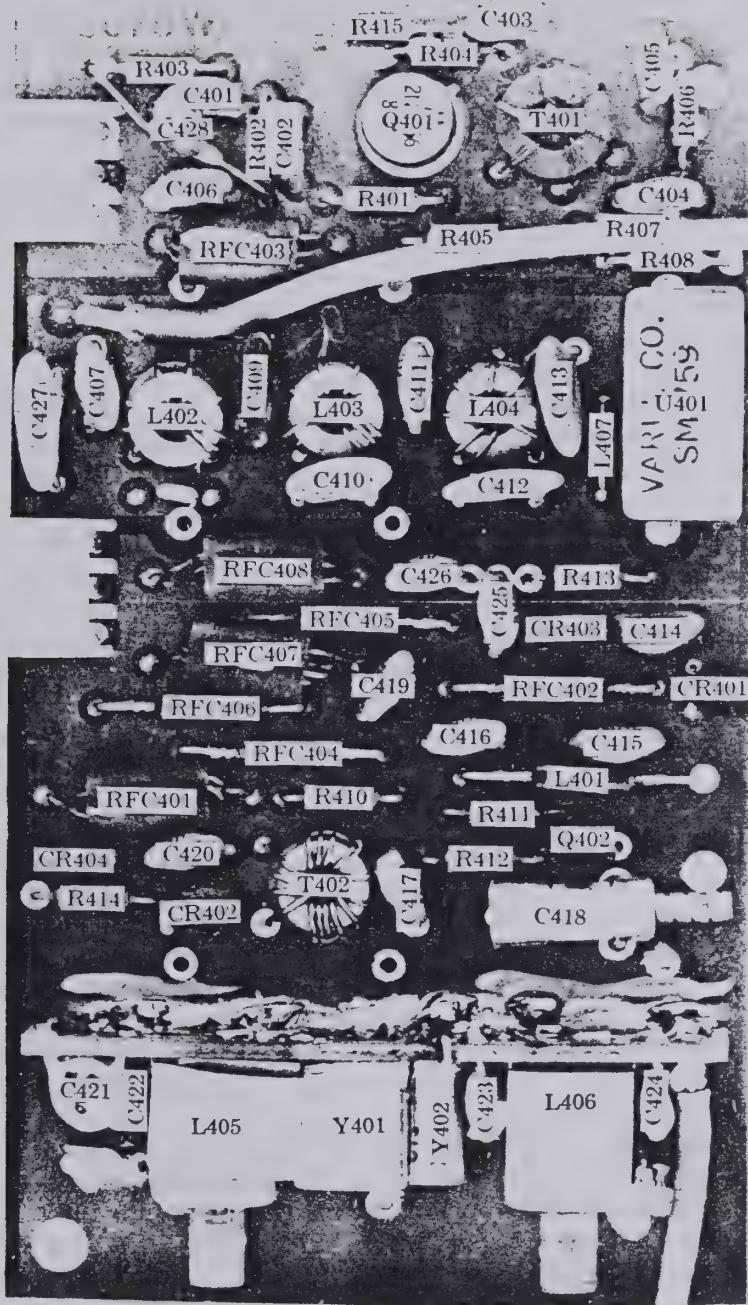

Fig. 2-7 Up-Converter Board Pictorial

## 2-5. VCO BOARD

The VCO Board provides the injection signal to the Up-Converter Board (Section 2-4.), and includes the phase detector and loop filter portions of the synthesizer. Refer to figure 2-10 for schematic and figure 2-9 for parts list information.

The VCO actually consists of two oscillators; one for low band (0-15 MHz) operation, and one for high band (15-30 MHz) operation. The two oscillators are quite similar in design, and the following discussion of the low band VCO can be applied to the high band VCO as well.

Q501 and Q502 form a push-pull oscillator which is tuned by L501 and varactors CR503-CR506. The high band VCO uses one less varactor, since the operating frequency is higher. Power for the oscillator is obtained from the VCO select line, which comes from the bandswitch. A 5 VDC regulator, U501, is used to insure a well regulated and filtered power source. CR503-CR505 are controlled by the coarse tune line from the phase detector circuitry, and CR506 is controlled by the fine tune line. Two control lines are required to insure that the VCO will always tune to the correct frequency.

The VCO output is coupled through a buffer stage, Q503, and a PIN diode, CR507, to T503, which provides additional isolation between the VCO and other circuits in the transceiver. A sample of the output of T503 is connected through R514 to the DR-7 for frequency readout purposes. T504 splits the output of T503, and the resulting outputs drive the Up-Converter and Translator Boards.

The low band VCO tunes between 48.05 and 63.05 MHz, corresponding to an operating range of 0 to 15 MHz. The high band VCO tunes between 63.05 and 78.05 MHz, corresponding to an operating range of 15 to 30 MHz.

Phase detector U503 compares the 500 kHz reference from the PBT/ Reference Board (Section 2-10) with the output of the programmable divider on the Translator Board (Section 2-6). The phase detector output is filtered by R521, R522 and C538, and amplified, inverted and filtered by U504A and associated components. The output of U504A is the fine tune line.

U504B is biased by R538 and R539 to amplify the fine tune line when it exceeds 15 volts, indicating that it is approaching the end of its range. The output of U504B is the coarse tune line. Large excursions of this line cause CR515/517 or CR516/518 to conduct to allow a fast slew rate. When the synthesizer loop is locked, the diodes cease to conduct, allowing R533 and C524 to filter the coarse tune line.

When the synthesizer loop is out of lock, pulses are produced by the phase detector at pin 1. These pulses are amplified by Q507, and integrated by R527 and C543 to produce a dc level. C539 is used to filter noise spikes from the output of Q507 during the locked state. The dc level produced by this circuit is used to turn on Q508, thus providing a ground at pin 10 of the circuit board during out-of-lock conditions. This ground is applied to the P.A. disable input of the LPF Module (Section 2-14) to prevent the transmission of spurious signals.

Alignment of the VCO Board consists of setting L501 and L502 for proper oscillator range, and is covered in Section 3. If parts replacement is required, be sure to replace the shield and ground clip exactly as installed at the factory to insure proper synthesizer operation. In addition, note that the oscillator transistors must be replaced in matched pairs in the high and low band VCOs.

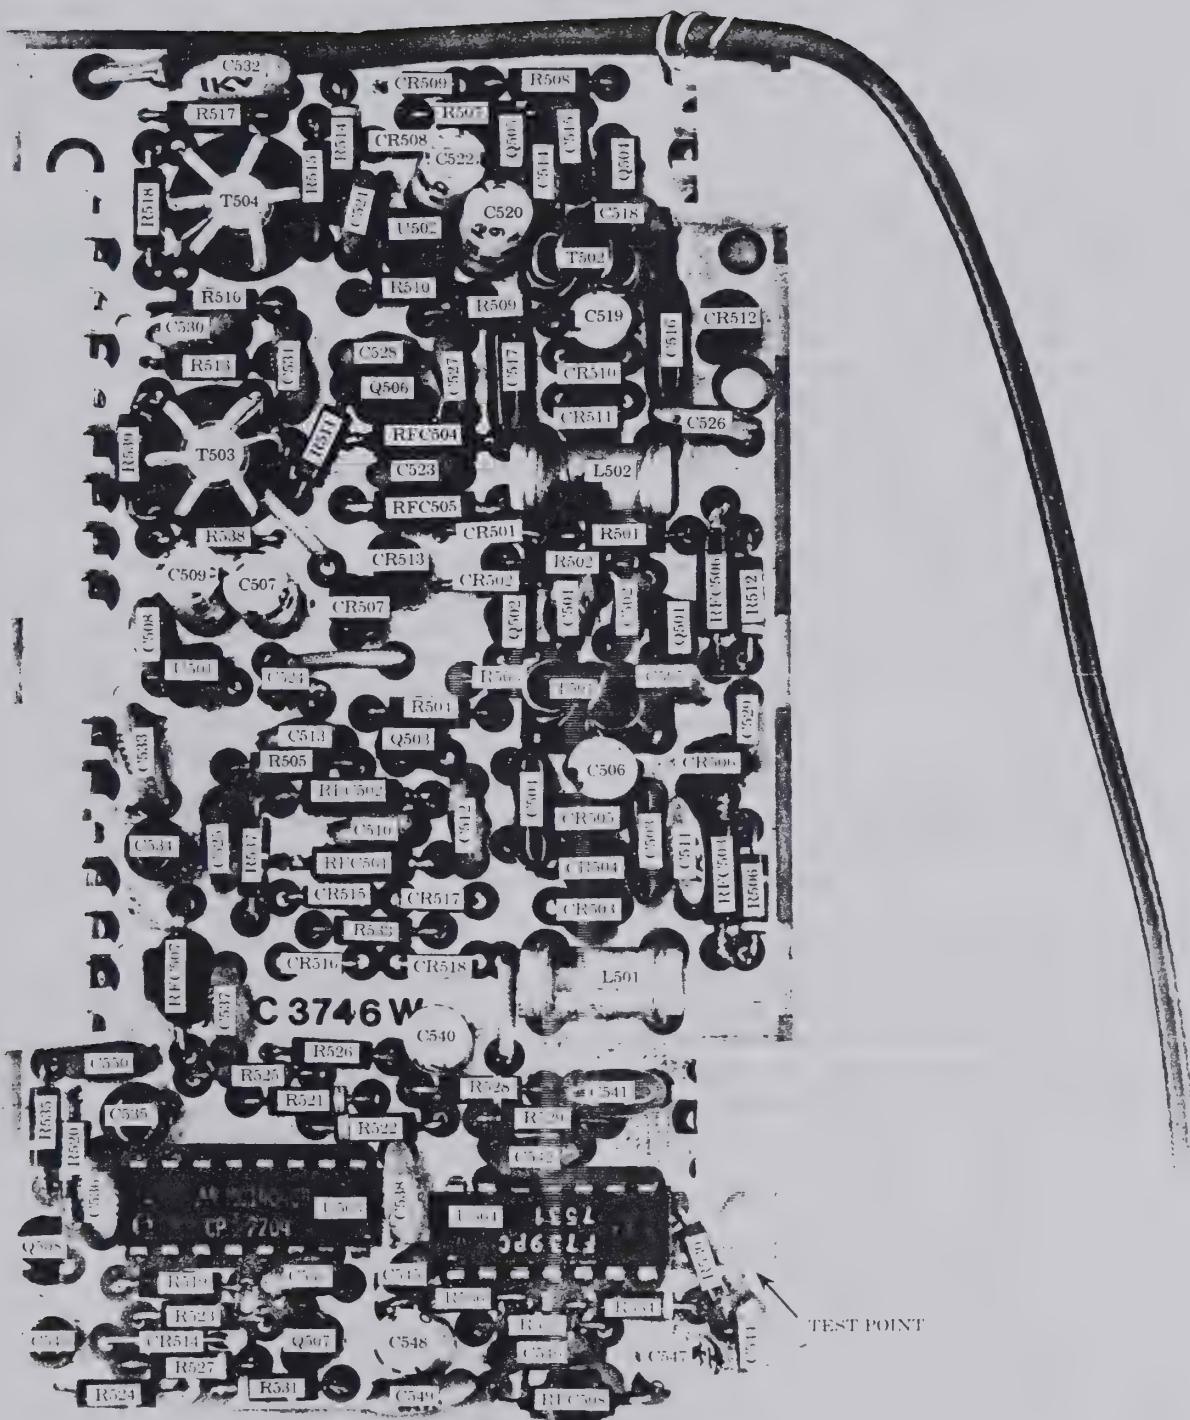

Fig. 2-9 VCO Board Pictorial

## 2-6. TRANSLATOR BOARD

The Translator Board combines the 40 MHz signal from the Passband Tuning/Reference Board, the 5.05-5.55 MHz PTO output and the 48.05-78.05 MHz VCO signal to create an input to the programmable divider. The output of this divider is routed to the phase detector on the VCO Board (Section 2-5) for frequency and phase correction of the VCO. Refer to figure 2-12 for schematic and figure 2-11 for parts list information.

The 5.05-5.55 MHz PTO signal is applied to one input of a double balanced mixer consisting of T604, T605 and CR605-608. The 40 MHz signal from the PBT/Reference Board is amplified by Q604 and applied to the other input of this mixer. The resulting 45.05-45.55 MHz signal is filtered by a bandpass filter consisting of L609-L611 and C623-C629, and routed to one input of a double balanced mixer consisting of T602, T603 and CR601-CR604. The other input of this double balanced mixer is connected to the output of the VCO Board, which varies from 48.05-78.05 MHz.

The output of this mixer is a signal which varies from 3 to 32.5 MHz, depending on the range of operation. This signal remains at a constant frequency for any selected 500 kHz segment, since the VCO frequency is forced by the phase detector to track the PTO frequency.

The 3-32.5 MHz signal is passed through a low-pass filter to remove undesired mixing products, amplified by Q603 and Q602 and buffered by Q601. This signal processing is required in order to achieve a sufficient level to drive the programmable divider. The programmable divider is comprised of U601 through U604, and is programmed to divide by a whole integer between 6 and 65, depending on the 500 kHz range selected. Programming information comes from the Digital Control Board (Section 2-2) and is modified by the DR-7 frequency programmer when this accessory is installed. Load number information to the Translator Board is present on pins 41-49 (the top connector) and is coded in BCD. The least significant digit of the load number is connected to pins 41-44, and the most significant digit to pins 46-49.

The output of the programmable divider, which is 500 kHz when the synthesizer is locked, is connected via the Parent Board to the phase detector on the VCO Board.

Alignment of the Translator Board consists of aligning the 45.05-45.55 MHz band-pass filter, and is covered in Section 3. Note that the shields on the board need not be removed for alignment. If parts replacement is required, be sure to replace all shields and ground clips to insure proper performance.

## 2-7. 2ND MIXER BOARD

In receive, the 2nd Mixer Board boosts the 48.05 MHz 1st IF signal level in a gain-controlled amplifier and converts it to the 5.645 MHz 2nd IF. In transmit, the 5.645 MHz transmit IF signal is converted to 48.05 MHz and amplified for additional conversion in the Up-Converter. Refer to figure 2-14 for schematic and figure 2-13 for parts location information.

48.05 MHz 1st IF signals from the Up-Converter are routed through CR701 to the input of amplifier Q702. CR701 is turned on by +10R via RFC702, RFC703, and R708. CR702 is biased off, since R720 is a common ground return. C710, C711 and L701 form an input matching network. AGC is applied to Q702 via R707. The output of Q704 is tuned by C721 and L703, and coupled to one input of a double balanced mixer via C722 and CR703, which is turned on by +10R via RFC707. CR704 is biased off, since R726 is a common ground return.

The injection for the mixer is a 53.695 MHz (nominal) signal which is developed on the PBT Board (see Section 2-10). This signal is amplified by Q701, the output of which is tuned by C705 and T701, and connected to the injection input of the mixer via C707.

The double balanced mixer is a diode ring type, consisting of CR707, CR709, CR711, CR713, R732, R733, R734, R735 and transformers T703 and T704. A series diode and resistor are used in each leg to increase the dynamic range of the mixer. In receive, the output of the mixer is the difference of the 53.695 MHz injection and the 48.05 MHz IF signal, or 5.645 MHz. This output is coupled to pin 19 via CR705 and C726. CR705 is turned on by +10R via RFC708. The voltage developed across R719, the common ground, back biases CR706.

In transmit, the 5.645 MHz signal from the ALC attenuator on the 2nd IF/Audio Board (Section 2-11) is applied to pin 1. It is coupled to one input of the mixer via CR706, which is turned on by +10T via RFC709. CR705 is biased off by the voltage developed across R719. The difference frequency between the 53.695 MHz injection and the 5.645 MHz IF signal is the 1st IF, or 48.05 MHz. This signal is coupled out of the mixer via CR704, which is turned on by +10T via RFC706. CR703 is biased off by the voltage developed across R726.

The 48.05 MHz transmit IF signal is amplified by Q703 to a level sufficient to drive the Up-Converter. The output of Q703 is tuned and matched by L702, C729, and C730, and coupled to the Up-Converter via CR702, which is turned on by +10T.

Alignment of the 2nd Mixer Board is covered in Section 3 of this manual.

## **2-12. JUMPER BOARD**

The Jumper Board consists of 2 CMOS integrated circuits, U1201 and U1202. These IC's are high current hex buffers. They buffer the CMOS output levels of the digital control board which in turn drive the translator board. Note the input code (12 pin connector) should be the same as the output code (9 pin connector). However, the output pin directly across from the input is not necessarily the same code bit. See figure 2-24 for schematic and figure 2-23 for parts list information.

Fig. 2-23 Jumper Board Pictorial

## 2-13. HIGH-PASS FILTER MODULE

The High-Pass Filter Module consists of three printed circuit boards; a filter board (assy. 1300), a front switch board (assy. 1400) and a rear switch board (assy. 1500). In addition, the module provides for mounting the ALC Board, which is described in Section 2-15. Refer to figure 2-28 for schematic and figures 2-25 through 2-27 for parts list information.

The front switch board accepts the antenna coax from the Up-Converter Board (Section 2-4). S1401 (front) connects this coax through C1402 to one of seven high pass filters. S1401 is positioned by the bandswitch shaft. The 25 kHz calibrator signal is connected to the Up-Converter input via switching diodes CR1401 and CR1402 in the calibrate mode. The VLF antenna input from rear panel accessory connector is coupled to the Up-Converter input through C1403 and R1404. R1403, R1405 and R1406 are used to lower the transmitter ALC threshold in the 21 and 28.5 MHz bandswitch positions. S1401 (rear) provides a momentary ground impulse for band-change information to the DR-7.

On the rear switch board, S1501 connects one of the seven high pass filters to C1503, which couples to a PIN diode transmit/receive switch. This switch couples the high pass filters to either the rear panel External Antenna jack via CR1502 and CR1503 or to the Power Amplifier Module via CR1501. The PIN diode switch is controlled by 13.6 VDC switched by the relay in the Low-Pass Filter Module (Section 2-14).

The high-pass filter board contains seven filters. Each filter corresponds to one bandswitch position except for the two lowest bands which share one filter. The approximate cut-off frequencies of these filters are:

BAND	FREQUENCY RANGE	CUT-OFF FREQUENCY
1 & 2	1.5-3.0 MHz	1.75 MHz
3	3.0-4.5 MHz	2.7 MHz
4	4.5-7.0 MHz	4.0 MHz
5	7.0-10.0 MHz	6.4 MHz
6	10.0-15.0 MHz	9.0 MHz
7	15.0-22.0 MHz	13.5 MHz
8	22.0-30.0 MHz	20.0 MHz

Note that the cut-off frequency of the band 1 and 2 filter is above the lowest frequency of interest. This is necessary to provide sufficient rejection to strong AM broadcast signals which can create interfering intermodulation products in the 160 meter amateur band. As a result, sensitivity and power output may be degraded below 1.75 MHz.

Removal of the High-Pass Filter Module is accomplished by removing the ALC Board from the bottom (2 screws), removing the bandswitch knob and unsoldering the wires connected to the front and rear switch boards. Be sure to label each lead so that it can be correctly reinstalled. Remove the two screws holding the bandswitch detent in the rear panel and slide the switch shaft straight back until it clears the front and rear switch wafers. The module can then be pulled up out the top of the chassis. Reverse this procedure to install the module. Be sure to orient the notch in the switch wafers in the proper direction when reinstalling the bandswitch shaft.

The above procedure is somewhat time-consuming, and it is recommended only in those cases that absolutely require removal of the module. Note that most repairs can be accomplished in the radio, due to the open construction, especially when the ALC Board is removed.

The High-Pass Filter Module does not require alignment.

## 2-8. IF SWITCHING BOARD

The IF Switching Board provides transmit/receive switching for the 5.645 MHz signal path. Refer to figure 2-16 for schematic and figure 2-15 for parts list information.

In receive, +10 volts is applied to pin 24 which forward biases CR801 and reverse biases CR802. The DC current path is through RFC802, RFC801, CR801 and R801 which supplies the ground return point. At the same time, the receive 5.645 MHz signal is applied to pin 22. The receive signal path is thus from pin 22 through C801, which provides DC blocking, through CR801, C805 (DC blocking) to the

coax connector. In transmit, +10 volts is applied to pin 37 in AM, RTTY, LSB and USB modes. Now, CR802 is forward biased and CR801 is reverse biased. The 5.645 MHz double sideband signal is applied to pin 26 through C803 (DC blocking), CR802 and C805 (DC blocking) to the coax connector. In transmit the DC current path is through RFC804, RFC803, CR802 and R801 again provides the DC ground return point. Pins 40, 39, 27 and 23 are ground pins. Pin 38 provides +10 volts for noise blanker operation when the NB-7 optional noise blanker is installed.

The IF Switching Board does not require alignment.

## 2-9. IF SELECTIVITY BOARD

The IF Selectivity Board provides for the installation of up to four 5.645 MHz crystal filters of various bandwidths in the TR-7. One of these filters, which is 2.3 kHz wide at the 6 dB points, is supplied with the unit. The other three filter positions are for accessory filters, which are purchased separately.

Each of the filter positions is identical, with the same circuitry used for selection. Therefore, although the following discussion refers to the standard 2.3 kHz position, it can be applied to positions A, B or C as well. Refer to figure 2-18 for schematic and figure 2-17 for parts location information.

In receive, +10R is routed to pin 15 via the front panel BW switches, which are wired so the +10R is present on pin 15 when both switches are in the 'out' position. This voltage turns on series diodes CR903 (via R903, RFC901, and R901) and CR906 (via R905, RFC902, and R922). The same voltage back biases shunt diodes CR904 and CR905. In the unselected positions (A, B and C in this case), -5 volts from pin 38 causes the shunt diodes to conduct and the series diodes to be back biased. This has the effect of opening and isolating all signal paths except the desired path through the 2.3 kHz filter.

A 5.645 MHz signal from the Noise Blanker or IF Switching Board is coupled through C930 to a common input line. Since the series diodes in positions A, B, and C are back biased, the signal is routed through CR906, C908 and C907 to the 2.3 kHz filter. After filtering, the signal is coupled through C904, C902, CR903 and C901 to the output of the board, a coax to the 2nd IF/Audio Board.

In transmit, +10T is applied to pin 14. This forces the board to select the 2.3 kHz filter, regardless of the position of the front panel switches, which are driven from +10R. The TR-7, therefore, always transmits through the 2.3 kHz filter. It is very important that this filter not be moved to another position or exchanged for a filter with different characteristics, to insure proper transmitter operation.

When servicing the IF Selectivity Board, be sure to replace all shields and grounds, if removed, in the original locations. Failure to do so may seriously degrade the ultimate selectivity of the crystal filter, resulting in signals outside the desired passband 'leaking around' the filters.

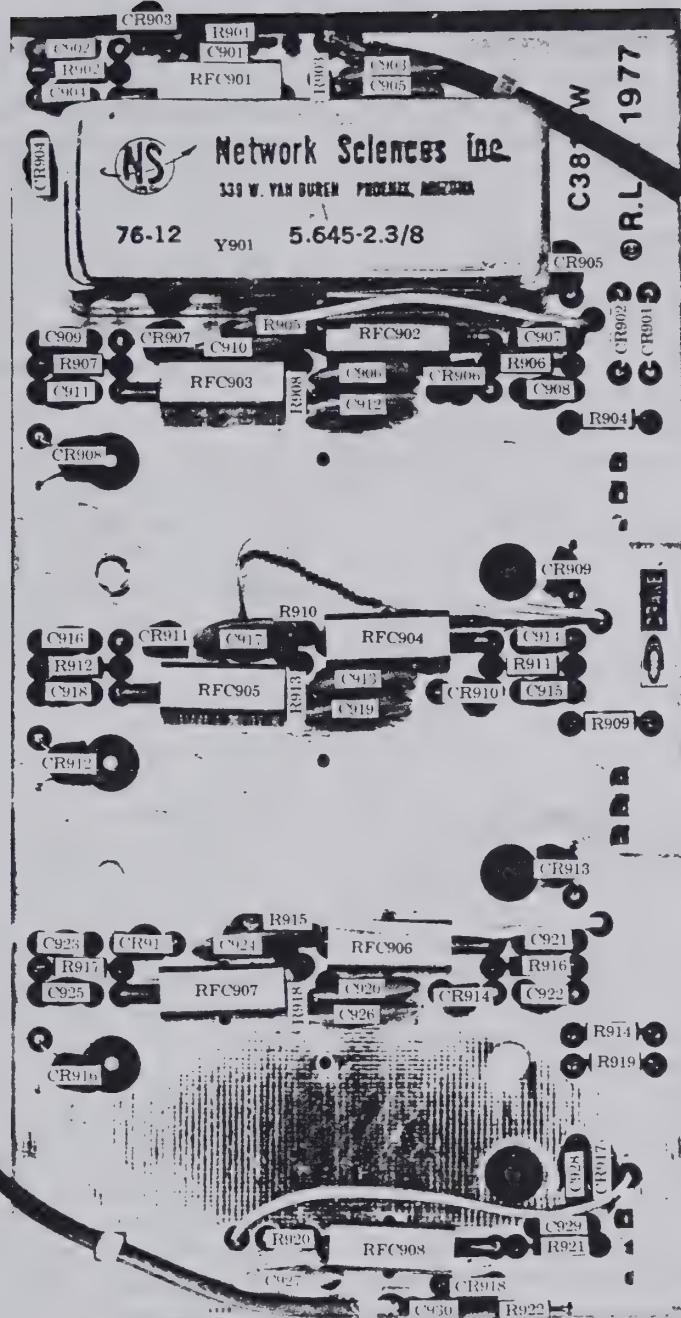

Fig. 2-17 IF Selectivity Board Pictorial

## 2-10. PASSBAND TUNING/REFERENCE BOARD

The Passband Tuning/Reference Board contains a 40 MHz crystal oscillator (master reference), dividers to obtain a 500 kHz reference and 25 kHz calibrator signals and a 13.695 MHz (nominal) VCXO. In addition, the board includes mixers to generate the 53.695 MHz 2nd L.O. and 5.645 MHz BFO signals, and circuitry to accomplish mode switching and electronic passband tuning. Refer to figure 2-20 for schematic and figure 2-19 for parts location information.

Q1001 is a high stability 40 MHz crystal oscillator. The oscillator is set to exactly 40 MHz with L1001, and is designed to maintain this adjustment over long periods of time. The output of the oscillator is buffered by Q1002 to reduce the effects of varying load impedance on frequency. The output of the buffer is tuned by L1006, and coupled through C1016 to all associated circuitry.

500 kHz for the synthesizer phase detector (Section 2-6) is derived from the 40 MHz reference by coupling the reference signal to driver transistor Q1006 through C1017. The output of Q1006 drives the  $\div 2$  section of U1002, which drives the  $\div 5$  section of U1003A, which drives the  $\div 8$  section of U1002. The net result is a  $\div 80$  function at pin 12 of U1002, which results in a 500 kHz signal. This signal is connected to board pin 10 for use in the synthesizer, and is also routed to the  $\div 5$  input of U1003B.

When the calibrator is activated by applying 10 volts to pin 5, Q1009 grounds the clear input, pin 14, of U1003B. This allows the  $\div 5$  section of U1003B to drive the  $\div 2$  section of U1003A, which drives the  $\div 2$  section of U1003B. The result is a  $\div 20$  function with a 500 kHz input which generates a 25 kHz signal rich in harmonics. The harmonics of this signal are injected into the antenna input of the receiver when the calibrator is enabled, and produce a calibration marker every 25 kHz.

The 40 MHz reference signal is also coupled to a power splitter, T1001. One output of this splitter is connected to pin 21 for use by the Translator Board (Section 2-6). A sample of this signal is coupled through R1062 for use by accessories. The other output of power splitter T1001 drives buffer stage Q1007, which boosts the signal to a level sufficient to drive one input of a double balanced mixer, consisting of T1002, T1003, and CR1002 through CR1005.

The second input to the mixer is the output of the 13.695 MHz (nominal) VCXO. This oscillator consists of Q1003 and buffer stage Q1005. The frequency is controlled by Y1002, a 13.695 MHz crystal which is pulled approximately  $\pm 3$  kHz by a varactor, CR1001, and L1005. The varactor is controlled by a voltage derived either from the front panel passband tuning control or from the passband controls located on the Power Supply/Regulator Board. The source in use is selected by the front panel PBT switch and/or by the MODE switch, and transmit/receive steering is accomplished by U1001, a quad switch. Actual operating frequencies of the oscillator in transmit or fixed passband receive are:

MODE	FREQUENCY
USB	13.6936 MHz
LSB	13.6964 MHz
CW	13.6942 MHz
RTTY	13.6975 MHz
AM	13.695 MHz (receive) 13.6936 MHz (transmit)

When the front panel PBT switch is on, the PBT control will tune the VCXO from approximately 13.692 to 13.698 MHz.

The output of the double balanced mixer is the sum of the reference and VCXO signals, or 53.695 MHz (nominal). The exact frequency, of course depends on the mode of operation selected. This signal is filtered by L1013 and C1042, and amplified by Q1010. The output of Q1010 is tuned by L1014 and C1050, and coupled through C1055 to pin 17 for connection to the 2nd Mixer Board (section 2-7).

The 5.645 MHz (nominal) BFO signal is also generated from the 13.695 MHz (nominal) VCXO. A portion of the VCXO signal is coupled through C1021, filtered by L1009 and C1024 and coupled through C1026 to one gate of Q1008, an autodyne converter. The other gate of Q1008 forms part of an 8.050 MHz crystal oscillator. C1030 is used to trim the crystal frequency, and C1029 is selected in test to center the trimmer range. The difference between the VCXO and 8.050 MHz is 5.645 MHz (nominal), which appears at the drain of Q1008. This BFO signal is filtered by C1034, C1043, C1038, L1011 and L1012, and coupled through C1037 to diode switching networks. These networks are used to switch the BFO signal to the product detector, balanced modulator and AM reinsertion circuit in the appropriate modes.

In the AM mode, +10R is applied to the base of Q1004 through R1009. This turns Q1004 on in AM receive, which removes the B+ supply to Q1008, thus shutting off the BFO signal. In AM transmit, Q1004 is turned off, allowing the BFO signal to be generated for AM reinsertion.

Troubleshooting the Passband Tuning/Reference Board is straight-forward. The 40 MHz oscillator should be checked first, since it affects all outputs. The 13.695 MHz VCXO should be checked next, and then the autodyne converter. In any case, an

analysis of which outputs are missing will isolate any problems to an individual oscillator.

Alignment of the board should be exactly in the sequence given in Section 3, which is:

1. 40 MHz oscillator
2. VCXO
3. 8.050 MHz oscillator

Failure to observe this sequence will almost certainly result in improper TR-7 operation due to frequency error and/or incorrect passband centering.

#### NOTES:

# TR-7 PASS BAND TUNING/REFERENCE OSCILLATOR BOARD

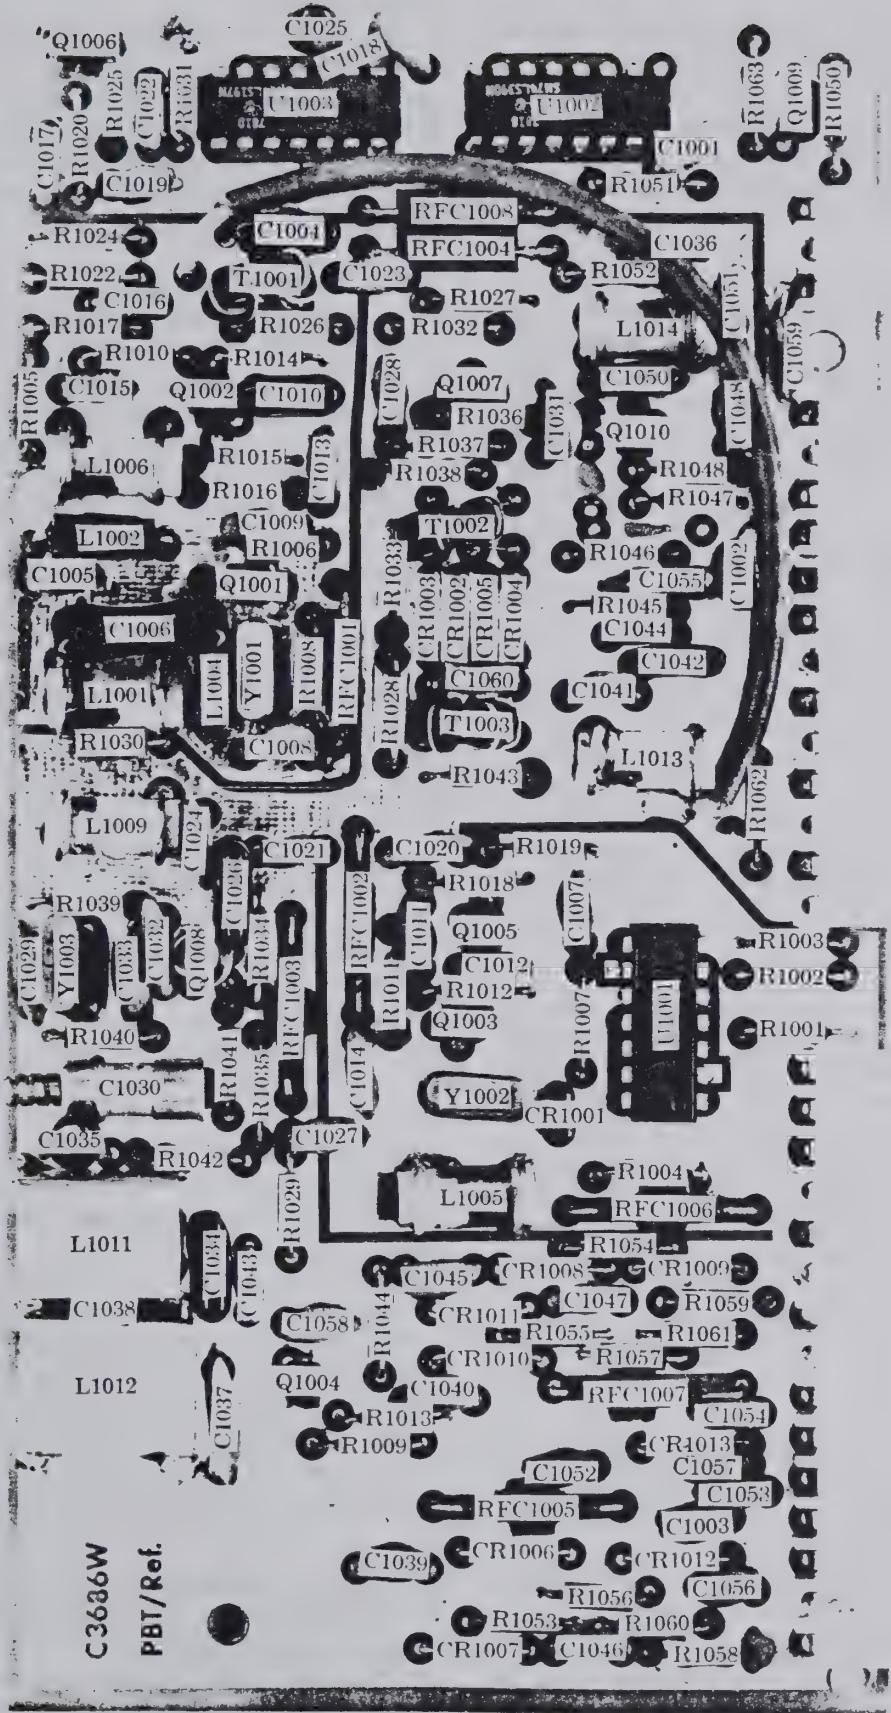

Fig. 2-19 PBT/Reference Board Pictorial

## 2-11. 2ND IF/AUDIO BOARD

The 2nd IF/Audio Board provides AGC controlled 5.645 MHz gain, signal demodulation, audio amplification and S-meter functions. It also includes a crystal controlled CW oscillator and a transmit IF summing amplifier. See figure 2-22 for schematic and figure 2-21 for parts location information.

In receive, 5.645 MHz 2nd IF signals from the IF Selectivity Board are connected to the input coax connector. This signal is matched to the input of the first stage of amplification, Q1101, by a transformer, T1101. The output of Q1101 is tuned by L1101 and coupled to the input of the second stage of gain, Q1106, through C1118. The output of Q1106 is tuned by L1102 and coupled to the input of the third stage of gain, Q1107, through C1127. The output of Q1107 is tuned by T1102, and coupled through this transformer to both the product and AM detectors.

In SSB, CW and RTTY modes, BFO injection is supplied from the PBT/Reference Board (Section 2-10) to the BFO amplifier, Q1112. The output of this amplifier is tuned by L1103, and coupled to the product detector via T1103. Audio is coupled out of the product detector through C1140 to pin 31, where it is routed to the top of the front panel AUDIO GAIN control. In the AM mode, the BFO is disabled, and 10 volts is supplied to the AM detector. +10T is also supplied to reduce T/R switching transients. The output of the AM detector is amplified by Q1111 and coupled by C1146 to the top of the front panel AUDIO GAIN control.

The wiper of the AUDIO GAIN control is connected to pin 29, and routed to the input of audio preamplifier Q1113. This stage receives B+ from either +10R (pin 14), or +10CW (pin 38). As a result, Q1113 is active only in receive, except in the CW mode. In CW it is on at all times to provide CW sidetone audio. The output of Q1113 is coupled to U1101, the audio output amplifier integrated circuit. The output of this device is coupled through C1159 to pin 27 to drive the loudspeaker or headphones. A sampling of the audio output is coupled through R1181 to pin 8 for use by the anti-vox circuitry (Section 2-3).

AGC is developed prior to detection by sampling the output of Q1107 through C1141. This signal is applied to the base of Q1108 which is biased to a point just below conduction. As the output of Q1107 increases (with increasing signal input to the receiver),

Q1108 starts to conduct, applying AGC voltage to the gates of Q1101 and Q1106. Stronger input signals cause Q1108 to conduct harder, thus developing a higher AGC voltage. This action holds the output of Q1107 essentially constant, which controls the drive to the detectors, holding the audio output of the receiver to a constant level.

AGC release time constants are controlled by selecting capacitors C1102-C1104 and C1156-C1158 via the front panel F/S pushbutton and mode switch. These capacitors are all charged through small series resistors to provide fast attack, and discharge through R1144, with the larger capacitors selected for longer release times. A sample of the AGC voltage is coupled through R1126 to a D.C. amplifier consisting of Q1105 and Q1102. This amplifier provides an output to control the gain of the 1st IF amplifier (see Section 2-7). In addition, the amplifier is used to drive the front panel S-meter in receive. R1105 is used to set full-scale sensitivity, and R1128 is used to establish the S-meter no signal reading. A small pedestal voltage is set by R1129 to allow the receiver to run a maximum gain under no signal conditions. Adjustment of these controls is described in the alignment procedure (Section 3). It is important to follow the exact sequence of adjustment to avoid improper AGC operation.

In the transmit mode, 5.645 MHz signals are summed at the base of Q1104. In CW, the transmit signal is derived from a crystal oscillator, Q1110, and buffer Q1109. These stages are keyed by Q1103. A portion of this signal is coupled through C1124, R1152, and CR1111 to Q1107 for sidetone generation. In the SSB and RTTY modes, the transmit signal is coupled from the IF Selectivity Board (Section 2-9) through T1101 and C1108 to the base of Q1104. In AM, the USB signal from this path is summed with the 5.645 MHz carrier to create an AM transmit signal.

The output of Q1104 is coupled to a PIN diode attenuator, CR1102. ALC voltage, developed by the ALC Board (Section 2-15), is used to vary the bias current in this diode, thus regulating the level of transmitter drive in all modes.

Alignment of the 2nd IF/Audio Board is covered in Section 3.

## TR-7 2ND IF/AUDIO BOARD

## 2-14. LOW-PASS FILTER MODULE

The Low-Pass Filter Module consists of four printed circuit boards; a front switch board (assembly 1900), a rear switch board (assembly 2000), and two filter boards (assemblies 1700 and 1800). The module provides low-pass filtering, relay switching and wattmeter functions. Refer to figure 2-32 for schematic and figures 2-29 through 2-31 for parts list information.

S1901 on the front switch board selects one of eight low-pass filters and connects the selected filter to the common of one section of K1901, which selects either the Power Amplifier output (in transmit) or the rear panel External Receiver jack (in receive). Other sections of K1901 provide linear amplifier and external receiver T/R switching, 13.6 VDC switching, and transmit-receive antenna isolation. K1901 is controlled by Q1901, which is turned on by +10T through R1901 and R1902. Note that if the P.A. disable connection is grounded, K1901 cannot be enabled. The P.A. disable line is grounded when the synthesizer is out of lock or when the R-7/RV-7 is in the SPOT mode, to prevent the transmission of spurious signals.

The two low-pass filter boards contain two section constant-k low-pass filters for each of eight bands. Each filter corresponds to one bandswitch position. The approximate cut-off frequencies of these filters are:

BAND	FREQUENCY RANGE	CUT-OFF FREQUENCY
1	1.5-2.0 MHz	2.2 MHz
2	2.0-3.0 MHz	3.3 MHz
3	3.0-4.5 MHz	5.0 MHz
4	4.5-7.0 MHz	7.8 MHz
5	7.0-10.0 MHz	11.0 MHz
6	10.0-15.0 MHz	16.5 MHz
7	15.0-22.0 MHz	24.0 MHz
8	22.0-30.0 MHz	40.0 MHz

On the rear switch board, S2001 selects one of the eight low-pass filter positions and routes the signal through wattmeter transformer T2001 to the rear panel ANT connector. Piston trimmer C1901 allows the wattmeter to be nulled into a 50 ohm non-reactive load. R2001 and R2002 are used to calibrate the forward and reflected wattmeter scales. Alignment of the wattmeter is covered in Section 3.

Note that the band one filter is not installed in a standard TR-7. Instead, the band one position is jumpered to the band two filter, which has an adequately low cut-off frequency to suppress the second harmonic of 1.8 MHz. If operation below 1.8 MHz is required, the band one filter must be installed to insure good harmonic suppression.

Removal of the Low-Pass Filter Module is accomplished in a manner similar to that described for the High-Pass Filter (Section 2-13). When reinstalling the bandswitch shaft, be sure to position the shaft grounding spring (located on the shield between the HPF and LPF) in such a manner to insure positive contact with the bandswitch shaft. In addition, do not force the switch shaft into the rotor or damage will result.

## 2-15. ALC BOARD

The ALC Board amplifies and combines the forward wattmeter, reflected wattmeter and linear amplifier ALC outputs, and provides an output for controlling the variable attenuator on the 2nd IF/Audio Board (Section 2-11). This circuitry thus controls the drive to the final amplifier, preventing flattopping and providing VSWR protection. Refer to Section 2-13 for schematic and parts list information.

In transmit, the forward wattmeter output is routed through CR1602 and R1611 to the non-inverting input of section C of the quad comparator U1601. Sections A and B of U1601 are operated as amplifiers, and are used to amplify and sum the reflected wattmeter and linear amplifier ALC outputs. Note that the linear amplifier ALC input is inverted to accommodate the conventional negative-going control voltage developed by most amplifiers.

The output of U1601B is summed with the forward wattmeter output through R1610. The result is a gain control signal representing forward power, VSWR (reflected power) and linear amplifier drive level at the non-inverting input of section C of U1601. R1613 sets a threshold on the inverting

input of this comparator, and when the drive controlling signal exceeds this threshold, a positive voltage is developed at the output. The threshold is set for the desired power output into a non-reactive 50 ohm load (the adjustment procedure is detailed in Section 3). Thus, as the reflected power increases (VSWR increases) or as the linear amplifier develops ALC output, the output of comparator U1601C becomes higher.

CR1603, R1617 and R1618, and C1611 form a fast attack, slow decay time constant to smooth rapid variations in the control voltage due to speech waveform variations. U1601D is used as a buffer, the output of which is routed through CR1604 to the variable attenuator. Voltage from the front panel CARRIER control is routed to this same point via CR1605 in the AM and CW modes. This arrangement allows the highest voltage to control the drive level, thus making the CARRIER control ineffective once ALC threshold has been reached.

Q1601 samples the ALC control voltage through R1616, and turns on the front panel ALC LED when the ALC system is in operation.

## NOTES:

## 2-16. POWER SUPPLY BOARD

The Power Supply Board provides +10, +5, +24 VDC regulated and -5 VDC unregulated. In addition, it provides the fixed passband tuning DC voltages for AM, RTTY, CW, LSB and USB. Refer to figure 2-34 for schematic and figure 2-33 for parts list information.

Unregulated 11-16 volts DC is applied to pin 9. Q2101, Q2102 and U2101 create the 10 volt regulator circuit from which all other voltages are derived. Q2101 is the pass transistor while Q2102 provides the base drive boost from U2101 to Q2101. R2109 and R2110 provide short circuit sensing. If the +10 VDC buss is shorted to ground the voltage drop across R2109 and R2110 increases. At 0.7 VDC, Q2103 turns on which forces U2101 to clamp the drive to Q2102 which in turn holds Q2101 at a fixed output of 5 amperes maximum short circuit current.

R2111, R2103, CR2101, and R2102 provide the error voltage feedback path to allow U2101 to maintain +10 VDC out. CR2101 is for temperature compensation. As the output line changes, the above components form a voltage divider network which allows U2101 to compare an internal reference of

approximately 7 VDC to the error voltage from R2103. +10 VDC output is on pin 10. +5 VDC regulated is provided by U2102 and is derived from the +10 VDC line. +5 VDC output is on pin 11.

The +24 VDC regulated and -5 VDC unregulated supplies are created by a DC to DC inverter circuit. Q2104 and Q2105 comprise an astable multivibrator which drives T2101 at approximately 23 kHz. Approximately 35 VDC is formed from the full wave bridge of CR2102 through CR2105. This DC voltage is filtered and applied to U2103 which provides regulated +24 VDC at pin 2. Simultaneously, -5 VDC is generated by a half wave rectifier CR2106, filtered and applied to pin 1.

The power supply board also contains voltage divider networks for the fixed passband tuning control lines. An adjustable divider is provided for each mode as follows:

MODE	DIVIDER NETWORK	OUTPUT PIN
AM	R2112, R2113, R2114	4
RTTY	R2115, R2116, R2117	5
CW	R2118, R2119, R2120	6
LSB	R2121, R2122, R2123	7
USB	R2124, R2125, R2126	8

Proper adjustment of these divider networks is covered in Section 3.

## 2-17. POWER AMPLIFIER MODULE

The Power Amplifier Module consists of two printed circuit boards; a predriver board (assembly 2200) and a power amplifier board (assembly 2300). The module accepts low-level transmit signals from the HPF Module (Section 2-15) and amplifies them to the desired output level. Refer to figures 2-36 and 2-37 for schematic and figure 2-35 for parts list information.

Transmit signals for the HPF Module are applied to Q2201 via an impedance stabilizing pad consisting of R2204, R2205 and R2206. R2207 allows the gain of Q2201 to be adjusted, providing gain control for the PA Module. The output of Q2201 is matched by trifilar transformer T2201 to the base of Q2202. The output of Q2202 drives Q2203, the collector of which is connected to the output of the predriver board. U2201, a 5 VDC regulator, is biased by R2201 and R2202 to provide a regulated 8 VDC source for biasing Q2201, Q2202 and Q2203 for class A operation to insure linearity. All B+ for the predriver board is obtained from the switched 13.6 VDC line, which is generated by the relay on the LPF Module (Section 2-14).

The output of the predriver board is connected to T2301 on the power amplifier board. C2301, L2301 and R2301 form a frequency compensation network to provide gain flatness across the operating range. T2301 matches the input of the power amplifier board to the bases of driver transistors Q2301 and

Q2302. The driver stage operates in push-pull, and is matched to the power amplifier stage by T2303. B+ is fed to the driver collectors through bifilar transformer T2302 to insure good balance. Q2303 and Q2304 form the push-pull power output stage. Each transistor is heavily swamped at the input and provided with low frequency inverse feedback to insure low frequency stability. The output of the power amplifier is matched to the 50 ohm input of the LPF Module by T2304.

Bias for the driver and power amplifier stages is derived from the switched 13.6 VDC line via 5 VDC regulator U2301. Driver bias is determined by the network consisting of Q2305, Q2306 and associated components. Both bias networks track the temperature of the power amplifier to prevent thermal runaway. B+ is present at all times on the collectors of the drivers and power amplifiers because the high currents involved are difficult to switch. No current is drawn in receive, however, because the bias for these stages is switched off.

Adjustment of the Power Amplifier Module is covered in Section 3. It is very important to note that the power amplifier board must be mounted on the heat sink for even the briefest periods of test or operation. Operation without the heat sink will result in damage to the power devices on this board.

*Fig. 2-37 Predriver P.A. Schematic*

## 2-18. PTO

The Permeability-Tuned Oscillator (PTO) provides a 5.05-5.55 MHz injection signal to the synthesizer circuitry of the TR-7. The VCO (Section 2-5) tracks the frequency of the PTO, thus allowing the operator to tune through any 500 kHz range via the front panel tuning control. The PTO has been very carefully calibrated and temperature compensated at the factory, and any attempt at repair or replacement of components will very likely destroy the calibration and/or compensation. It is highly recommended, therefore, that any PTO which requires attention be returned to the factory for proper repair.

It is possible to adjust the knob torque required to tune the PTO, should this become necessary. This is accomplished as follows:

1. Remove the two plastic end caps from the sides of the front panel. Note that these caps are not identical; there is a right and a left end cap.
2. Remove the DR-7, if installed.

3. Remove the top two screws on each side holding the front panel to the side rails, and loosen the bottom screws.
4. Remove the bandswitch knob.
5. Remove the two screws holding the bandswitch shaft detent to the rear panel and slide the bandswitch to the rear just enough to clear the front panel.
6. The front panel will now hinge down, exposing the PTO.
7. Refer to figure 2-38 and identify the wrench access hole in the rear of the PTO cover. Insert a long (at least 3") 3/32" ALLEN wrench straight through this hole, seating the wrench in the ALLEN set screw which serves as the shaft bearing. The proper wrench is available from the factory. Be sure to insert the wrench straight through the access hole, to avoid damaging any components inside the PTO.
8. Carefully adjust the set screw for the desired knob torque. Overtightening the adjustment screw must be avoided to prevent bearing damage.
9. Reverse the above procedure to reassemble the TR-7.

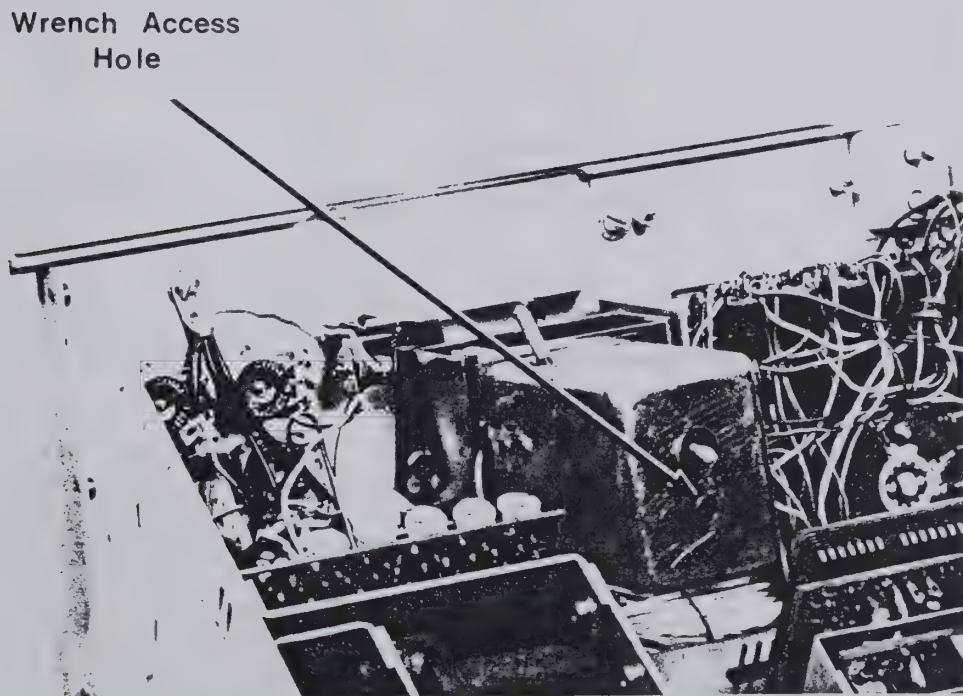

Fig. 2-38 PTO Torque Adjustment

## SECTION 3

### ALIGNMENT PROCEDURE

The following alignment procedure can be accomplished with a VTVM, RF Voltmeter, 60 MHz frequency counter and an accurate wattmeter. In addition, a good high-frequency (30-50 MHz) oscilloscope, two-tone generator, monitor scope and signal generator are recommended, but not required.

The procedure is structured in such a manner that it may be entered at any point and followed to conclusion. That is, if you are sure that all adjustments preceding those of interest are correct, you may start at the section which addresses the problem at hand. However, all sections following the starting point must be completed to insure proper operation. If any doubt exists, it is recommended that the entire procedure be executed.

It is not necessary to use the board extenders for any of the following adjustments. In fact, use of the extenders will distort the alignment settings. The board extenders should be used only for troubleshooting and repair.

#### 3-1. 10 VOLT ADJUSTMENT

Using an accurate voltmeter, adjust R2103 on the Power Supply/Regulator Board (Section 2-16) for exactly 10 VDC, measured on the 10 volt trace of the Parent Board (Section 2-1). Note that adjusting the 10 volt regulator will affect all circuits in the transceiver, thus requiring a full alignment.

#### 3-2. S-METER ADJUSTMENT

The S-meter adjustments are located on the 2nd IF/Audio Board (Section 2-11). These adjustments must be made in the AM mode (to prevent errors due to BFO leakage), and must be made in the order outlined below. Failure to do so will result in improper S-meter and AGC operation.

- a) Remove the rear card cage top cover.
- b) Select the AM mode, and remove any antennas.
- c) Turn the zero adjust, R1128, fully CW.
- d) Turn the AGC pedestal adjust, R1129, fully CW.
- e) Rotate R1129 CCW until the S-meter reading increases 2 S-units.
- f) Adjust R1128 for an S-meter reading between 0 and 1. Be sure that the S-meter is slightly above 0.
- g) Turn the front panel RF Gain control fully CCW.

- h) Adjust the sensitivity control, R1105, for a full scale S-meter reading of 80 dB over S-9.
- i) Rotate the RF Gain control fully CW and check to be sure the S-meter reads between 0 and 1. If not, repeat steps c through i.

#### 3-3. 40 MHz OSCILLATOR ALIGNMENT

Adjust L1006 on the PBT/Reference Board (Section 2-10) for maximum 40 MHz output on pin 21. Use an RF voltmeter, and measure this level on the Parent Board.

Connect an accurate frequency counter to pin 19 of the PBT/Reference Board and adjust L1001 for exactly 40 MHz. Note that any error in this adjustment will result in a calibration and readout accuracy discrepancy. Do not use pin 21 for this adjustment, since the load of the counter may cause the 40 MHz oscillator to shift frequency slightly.

Although adjustment with a frequency counter is preferred, it is possible to set the 40 MHz oscillator using WWV. Peak L1006 as described above, and tune to the strongest available WWV signal in your area. Place the radio in the AM mode, and wait until WWV is transmitting an unmodulated carrier. Enable the calibrator and carefully adjust L1001 for exact zero beat with WWV. This method requires that WWV be of comparable signal strength with the calibrator. As such, it may be necessary to select the proper time of day as well as frequency for your area to achieve the desired results.

#### 3-4. 13.695 MHz VCXO Adjustment

This adjustment should be performed accurately and exactly as outlined below to insure that the passband is correct in the various modes of operation. Be sure that the 40 MHz oscillator is on frequency before attempting this adjustment.

- a) Depress the front panel PBT button.
- b) Position the front panel PBT control at the center of rotation (indicator straight up).
- c) Connect a frequency counter to pin 17 of the PBT/Reference Board and adjust L1005 for exactly 53.695 MHz. This is the 2nd L.O. frequency, which is the sum of the 40 MHz and 13.695 oscillators, thus it is important that the 40 MHz oscillator be on frequency.

### 3-5. 8.05 MHz Oscillator Adjustment

Before adjusting this oscillator, be sure that the 40 MHz and 13.695 MHz oscillators are on frequency. Failure to do so will result in improperly adjusted BFO frequencies and undesirable operating characteristics.

- a) Depress the front panel PBT button.
- b) Position the front panel PBT control at mid-range.
- c) Select any mode except AM (BFO must be on).
- d) Connect a frequency counter to pin 40 of the PBT/Reference Board and adjust C1030 for exactly 5.645 MHz. If additional range is required, C1029 may be changed to obtain the proper results.

### 3-6. FIXED PASSBAND ADJUSTMENT

Before attempting the following adjustments, be sure that the 40 MHz, 13.695 MHz and 8.05 MHz oscillators are properly adjusted. If any of these signals are off frequency, improper operation will result.

The fixed passband adjustments are located along the top of the Power Supply/Regulator Board. Refer to Section 2-16 for parts location data.

Connect a frequency counter to pin 40 of the PBT/Reference Board and make the following adjustments with the front panel PBT control off:

- a) In the USB mode, adjust R2125 for 5.6436 MHz.
- b) In the LSB mode, adjust R2122 for 5.6464 MHz.
- c) In the CW mode, adjust R2119 for 5.6442 MHz.
- d) In the RTTY mode, adjust R2116 for 5.6475 MHz.

Move the counter to pin 17 of the PBT/Reference Board, select the AM mode, and adjust R2113 for 53.695 MHz.

### 3-7. VCO ALIGNMENT

The alignment of the high and low VCO can be checked very quickly if the DR-7 is installed. Set the AUX PROGRAM switch to NORM, the BAND to 14 MHz, and press the FIXED RCV button. The display should count up in frequency, and go to approximately 17 MHz. Set the BAND to 21 and press the FIXED RCV button. The display should

go to approximately 32 MHz. If these results are obtained, the VCO does not require alignment.

If alignment is indicated, or if the DR-7 is not available for the above test, perform the following steps to align the VCO. Refer to Section 2-5 for parts location.

- a) Attach a VTVM to the alignment test point shown in figure 2-9.
- b) Set BAND switch to 14 MHz and set the PTO to 500.
- c) The VTVM should indicate  $16.0 \pm 0.5$  VDC. If not, adjust L501 for exactly 16 VDC.
- d) Set BAND switch to 28.5 MHz (leave PTO at 500).
- e) The VTVM should indicate  $15.0 \pm 0.5$  VDC. If not, adjust L502 for exactly 15 VDC.

In order to gain access to L501 and L502, the DR-7 and front circuit card shield cover must be removed. The Jumper Board must be installed in place of the DR-7, using the appropriate board extenders.

### 3-8. TRANSLATOR ALIGNMENT

Translator alignment should be necessary only when parts on the circuit board have been replaced. Remove the DR-7 and front circuit card shield cover, and install the Jumper Board (on board extenders) in place of the DR-7. Perform the following steps in the order listed to insure correct alignment:

- a) Set BAND switch to 1.5 MHz and set PTO to 500.
- b) Connect an RF voltmeter to the alignment test point indicated in figure 2-11.
- c) Back out the slug in L610 two turns, or until RF voltage decreases by 50%.
- d) Peak L609 and L611 for maximum.
- e) Peak L610 for maximum—do not retune L609 and L611.

### 3-9. RECEIVER ALIGNMENT

The receiver must be aligned with all shields fastened in place. All adjustments are accessible through the shields and they are labelled with the appropriate designators. Perform each step of the following procedure in the order listed:

- a) Select the USB mode.
- b) Depress the PBT pushbutton.

- c) Center the PBT control.
- d) Select the 28.5 MHz band.
- e) Depress the CAL pushbutton and tune the receiver to zero beat with the calibrate signal.
- f) Select fast AGC.
- g) Peak C418 on the Up-Converter for maximum S-meter reading.
- h) Peak L701, C716, and L703 on the 2nd Mixer for maximum S-meter reading (may be labelled L801, C818 and L803 on early units).
- i) Peak T1101, L1101, L1102 and T1102 on the 2nd IF/Audio Board for maximum S-meter reading.
- j) Turn off the calibrator and rotate the PBT control through its range while watching the S-meter. If any movement is detected, adjust R1136 to eliminate it.

A properly aligned receiver should read approximately S-9 on the calibrator signal on 10 meters. If a calibrated signal generator is available, check to see that S-9 is approximately  $30 \mu$  V on all bands.

### 3-10. TRANSMITTER ALIGNMENT

Proper adjustment of the transmitter is important to insure stable operation. Carefully follow the sequence of adjustments below, and be sure to complete the next two sections (3-11 and 3-12). Note that the rear shield cover must be removed in order to make some of the following adjustments. Be sure to replace this cover after alignment.

- a) Select the AM mode.
- b) Select the 28.5 MHz band.
- c) Key the transmitter into a 50 ohm dummy load, using the PTT.
- d) Adjust the carrier for 30 watts or less. Keep the carrier below 30 watts during the following adjustments.
- e) On the 2nd Mixer, peak C705 and L702 for maximum power.
- f) On the PBT/Reference Board, peak L1013, L1014, L1009, L1011 and L1012 for maximum power.

### 3-11. WATTMETER NULL ADJUSTMENT

Proper adjustment of the wattmeter null requires a 50 ohm nonreactive dummy load. Failure to use such a load will result in erroneous wattmeter readings and improper ALC action.

Select the 14 MHz band, and set the mode switch to CW. Remove the bottom cover and attach a VTVM to the reflected power input of the ALC board (see

Section 2-15). Connect the dummy load and key the transceiver. Adjust the carrier to approximately 100 watts output, making sure the ALC light is not indicating. Adjust C1901 (through the rear panel) for minimum VTVM reading-typically less than 0.5 VDC.

### 3-12. ALC ADJUSTMENT

The ALC and transmitter gain must be set as outlined below to insure proper transmitter operation and to provide protection to the final amplifier.

- a) Select the 14 MHz band.
- b) Select the CW mode.
- c) Connect a 50 ohm non-reactive dummy load and, if available, an accurate wattmeter.
- d) Key the transceiver and turn the carrier control fully CW.
- e) Set R1613 on the ALC Board (Section 2-15) for 140-150 watts output power.
- f) Unkey the transceiver and select the 28.5 MHz band.
- g) Key the transceiver and adjust R2227 on the Predriver Board (Section 2-17) to the point where the ALC light just comes on.

#### NOTE

Do not set R2227 any higher than necessary, or transmitter instability will result.

- h) Check all bands to be sure that the ALC light comes on at full power output. If a two-tone generator is available, check for flattopping on all bands. If any is noted, slightly decrease the setting of R1613 to eliminate it.

### 3-13. WATTMETER CALIBRATION

An accurately calibrated wattmeter and a 50 ohm non-reactive dummy load are required to complete this procedure.

- a) Select the 14 MHz band.
- b) Select CW mode and key the transceiver.
- c) Adjust the carrier control for 100 watts output into the 50 ohm load as measured on the external wattmeter.
- d) Adjust R2001 on the LPF module (Section 2-14) for 100 watts indicated on the internal (front panel) wattmeter.
- e) Remove the coax from the TR-7 antenna connector.
- f) Adjust R2002 on the LPF module so that the wattmeter reads the same in the forward and

reflected wattmeter positions. This adjustment is most accurate if the carrier control is reduced to the point where the ALC light just extinguishes.

#### NOTE

The following adjustments can be made without any regard to prior alignment or order, since they are independent of other circuitry in the TR-7.

#### 3-14. CW SIDETONE FREQUENCY ADJUSTMENT

Adjust C1136 on the 2nd IF/Audio Board for an 800 Hz sidetone in CW when the TR-7 is keyed. C1136 is accessible through the rear panel key jack, and a metal screwdriver can be used to key the radio while making this setting.

#### 3-15. CARRIER BALANCE ADJUSTMENT

Adjust R349 on the Transmit Exciter Board (Section 2-3) for minimum output in LSB and USB with the TR-7 keyed and the microphone gain at minimum. A separate receiver is recommended as a sensitive indicator for this adjustment. An RF Voltmeter or sensitive oscilloscope connected to the antenna terminal may also be employed.

#### 3-16. RIT CENTERING ADJUSTMENT

Zero beat the calibrate signal with the RIT on and set to the center of its range (indicator straight up). Turn off the RIT and adjust R-24 on the Parent Board for zero beat. On early radios, the DR-7 must be removed and replaced with the Jumper Board to make this setting. Later radios have an access hole on the bottom of the Parent Board.

## SECTION 4 ACCESSORIES

### 4-1. DR-7 DIGITAL READOUT

The DR-7 provides two major functions for the TR-7 — full receiver coverage from 1.8-30 MHz and digital frequency display. The two sections are completely independent. A failure in one section will usually not affect the other. A careful observation of the symptoms and a few measurements will isolate the fault to a major section. See table 4-1 before removing DR-7. Refer to figure 4-1 for the parts location and figure 4-2 for the schematic.

All waveforms on the schematic are taken with the TR-7 tuned to 1.9500 MHz. All waveforms are taken with the oscilloscope set to AC trigger on the first edge shown on the schematic, i.e.: rising or falling edge. An oscilloscope with at least a 100 MHz bandwidth is required to faithfully reproduce some signals. Some signals, especially in the counter and display section, may be displayed with jitter when viewed on an oscilloscope without trigger hold-off. All levels are 0V and 5V high unless noted otherwise.

Section 4-1.1 contains the detailed theory of operation for the full coverage section and 4-1.2 for the digital frequency display. U9001 (6) refers to

I.C. #9001, pin 6. Ground and supply connections are #7 and #14 for 14 pin I.C.'s, #8 and #16 for 16 pin I.C.'s, and #12 and #24 for 24 pin I.C.'s, unless noted otherwise.

If trouble is suspected with the full coverage section, remove the DR-7 and replace it with the Jumper Board for verification. If a component must be removed, **USE CARE**. Wicking braid and a low wattage, grounded soldering iron are recommended for component removal.

LED displays are matched for brightness. If a failure is determined to be in the display, replacement of both is advised. The recommended procedure to remove the display is to cut the connector pins close to the DR-7 P.C. Board. Remove the pins and clear the holes of solder. To replace the display, solder the displays to a new connector. The displays should be flush with the connector. The two digit and four digit displays are spaced apart one pin. Insert the display and connector assembly into the DR-7 board. Space the connector body .1 inch (.254 cm) using a drill bit or other spacer. Solder the connector to the DR-7 board and remove the spacer.

TROUBLESHOOTING GUIDE

Check For:  
Proper DR-7 installation.  
Loose or improperly installed connectors.  
Proper function of NORM/EXT switch.  
Proper operation of STORE pushbutton.

Symptom — digits and decimal point blanked  
Check — U9019, U9028, Q9013, Q9011  
Symptom — digits blanked but decimal point on  
Check — U9031, U9029, U9016, U9032,  
Q9002, Q9003  
Symptom — random counting, synthesizer  
unlocked  
Check — full coverage section or TR-7  
Symptom — random counting, synthesizer  
locked  
Check — U9016, U9012, U9011  
Symptom — one segment on or off in all digits  
Check — U9032, U9029, LED Display  
Symptom — one digit incorrect  
Check — counter and latch for that digit

#### 4-1.1 FULL COVERAGE SECTION

The major functions of the full coverage section are to take the synthesizer load number provided by the digital control board and increment or decrement the load number with the UP or DOWN front panel switches within the limits of the input low pass and high pass filters and to enable the transmitter on the amateur bands. When the bandswitch is changed from one band to another, U9002 (1) is momentarily grounded via the wire going to the high pass filter module. If the AUX PROGRAM switch is in NORM, U9002 (3) will go high and trigger U9004, a one shot. The negative pulse out of the one shot will cause U9002 (4) to go high, latching the BCD load number present at pins 2/41 through 2/48 into the programmable up-down counters U9005 and U9006. The one shot insures that the data from the band switch is valid before latching the number. In AUX PROGRAM switch positions 1-8 U9002 (6) is held low, causing U9002 (4) to stay high. This allows any load number at the counter inputs to be fed directly to the outputs. The outputs of the counters are buffered by the high current drivers U9007 and U9008 and applied to the divide by N inputs of the translator board. When the UP or DOWN pushbutton is depressed, a negative pulse is generated at the output of one shot U9004 (7) and applied to the clock inputs of the counters. When the DOWN pushbutton is depressed U9002 (11) remains low, the counters will decrement by one and the VCO frequency will increase. The load number is fed to the inputs of READ ONLY MEMORY U9003. When a load number corresponding to a band edge is programmed, U9003 (12) and/or U9003 (11) will go low and disable the UP or DOWN latches. Refer to paragraph 1-3.3 to determine the proper load number for a particular 500 kHz segment.

#### 4-1.2 COUNTER SECTION

The counter circuit can be divided into three major sections: the time base divider, the counter, and the display. The time base divider generates the signals required to gate the input signal into the counter, store the contents of the counters, and control the multiplexed information to the display section. The display section decodes and buffers the multiplexed information from the counter section and drives the LED display.

The TIME BASE DIVIDER is comprised of U9014, U9015, U9019, U9022, U9026, U9028 and

U9016. The 500 kHz synthesizer reference signal is divided by 5 by U9014 producing 10  $\mu$ S pulses. The 10  $\mu$ S pulses are applied to the divide by 10,000 circuit consisting of U9017, U9019, and U9022, and to flipflop U9026. After 100 mS, U9016 (13) will go low. At the next pulse from U9014, U9026 (1) will go low and U9026 (2) and U9015 (2) will go high, generating a strobe pulse at U9015 (10). On the second pulse from U9014 after the strobe pulse, a reset/load pulse is generated at U9016 (3). On the second pulse from U9014 after the reset pulse, a time base reset pulse is generated at U9016 (1). This pulse resets the dividers and sets U9026 (13) high. On the next pulse, U9026 (1) goes high and the sequence starts again. During the 100 mS gate time, the BCD output of U9019 is fed to 1 of 10 decoder U9028. The outputs of U9028 are used to multiplex the BCD information stored in the latches to the display section.

The COUNTER CIRCUIT consists of input amplifiers U9009 and U9010, gating circuits U9011 and U9012, and counting circuits U9013, U9017 through U9021, U9023 through U9025, U9027, and U9030. The VCO signal is amplified by U9010. The external input signal is amplified by U9009. U9011 selects which signal is applied to the gate circuit. When U9012 (7) goes high, U9012 (3) will go low on the next rising edge of the selected input signal allowing the signal to be passed to decade divider U9013. The outputs of U9013 are buffered and applied to Q9002, which amplifies the ECL level signal to a TTL level. The TTL signal is applied to decade counter U9017 and then to U9019. The output of U9019 is applied to the programmable decade counter chain U9020, U9023, U9024, and U9027. The outputs of all of the counters feed latches. At the end of the gate time the BCD information is stored in latches U9018, U9021, and U9025 by the strobe signal from the time base divider section. After the strobe signal, the counters are either reset to all zeroes or loaded with an offset number by the reset/load pulse. When the DR-7 is operating in the NORMAL mode, the reset/load pulse is applied to pin 1 of the programmable counters and U9016 (5). U9016 (6) is grounded by the NORM/EXT switch preventing the load/reset pulse from resetting the counters. The counters will be preset to 5195, which will subtract the 48.05 MHz First IF from the VCO frequency. In the EXT mode the reset/load pulse is applied to both pin 1 and pin 9 of the programmable counters setting them to zero. When operating in the EXT mode and the

input frequency exceeds 99.9999 MHz, U9030 (13) will go high and U9030 (1) will be latched high by the strobe pulse. When the STORE pushbutton is depressed, the strobed pulse is grounded and the information in the latches is not updated by the counters.

The **DISPLAY SECTION** is comprised of U9028, U9029, U9031, U9032, Q9005 through Q9013, and the LED display. When U9028 (2) goes low, the BCD information stored in latch U9025B is applied to the BCD to 7-segment decoder U9029. The outputs of U9029 are applied to U9032. The outputs of U9032 sink current from the common anode LED display. At the same time, the outputs of U9025B are enabled, Q9005 is turned on by U9028 (2) supplying current to the left-most digit of the display. After D1 has been lit for 100 mS, U9028 (2) will go high and U9028 (3) will go low,

turning on Q9006 and enabling the information stored in U9028A to be decoded and applied to the cathodes. Each digit will be enabled sequentially for 100  $\mu$ S at a 1 kHz rate. Q9012 is turned on at D5 to illuminate the decimal point. If D1 is zero, U9029 (4), U9031 (1) and, if the counter has not exceeded 99.9999 MHz, U9029 (5) will go low and the leading zero will be blanked. U9031 (1) will remain low until a number other than BCD "0" is applied to the inputs of U9029. When the counter is operating in EXT and the frequency exceeds 99.9999 MHz, leading zeroes are not blanked. 100 MHz will display 00000.0 kHz. If power is applied without the 500 kHz input or if a failure should occur in the time base divider circuitry, the pulse at U9028 (1) will go away, causing Q9013 to turn off. When Q9013 turns off, Q9011, which supplies the ground to the display driver, will turn off preventing damage to the display.

#### NOTES:

## DR-7 DIGITAL READOUT

#### **4-2. AUX-7 AUXILIARY PROGRAM BOARD**

The AUX-7 Auxiliary Program Board is an accessory which allows the programming of up to eight 500 kHz ranges and/or eight fixed channels. These channels are selected by the front panel AUX PROGRAM switch, which applies 5 volts to pins 1-8 of the board for channel selection. All eight channels are identical in operation, so the following discussion for channel 1 can be applied to any channel.

Channel 1 is selected by applying 5 volts to pin 1 of the AUX-7 via the front panel AUX PROGRAM switch. This voltage is applied to pin 1 of the channel range module and to the anode of CR101 through R101. R101 sets the current through CR101, while R101 and C101 form an rf decoupling network. The current through CR101 effectively grounds one end of C102 and C103, thus enabling the channel 1 crystal (if installed).

The RTM-7 and RRM-7 range modules are diode arrays arranged in such a manner that pin 1 is connected to the anode of all diodes. The cathodes of the diodes are connected to module pins 2 through 14. Thus, when 5 volts is applied to pin 1,

approximately 4.3 volts will appear at all other pins of the module which have not been removed during range programming. In this manner, BCD data is supplied to the Digital Control Module for band and range control. Band information is present on AUX7 pins 9 through 12, and range information is found on pins 15 through 22.

When the TR-7 is placed in the FIXED mode, 10 volts is applied to pin 25 of the AUX-7. This voltage is applied through L101 (for rf decoupling) to the anode of CR109 thus enabling the fixed oscillator output, pin 24. At the same time, 10 volts is supplied to Q101, the fixed crystal oscillator stage, and Q102, the fixed output buffer stage, allowing these stages to operate. The output of the buffer (Q102) is routed through an attenuator consisting of R115, R116, and R117 to the anode of CR109, from which it is connected through the switching network on the parent board to the translator module in place of the PTO signal.

The only alignment required in the AUX-7 is the setting of C103, C106, C109, C112, C115, C118, C121, and C124, which are provided to set the eight fixed channel crystals exactly on frequency.

#### **NOTES:**

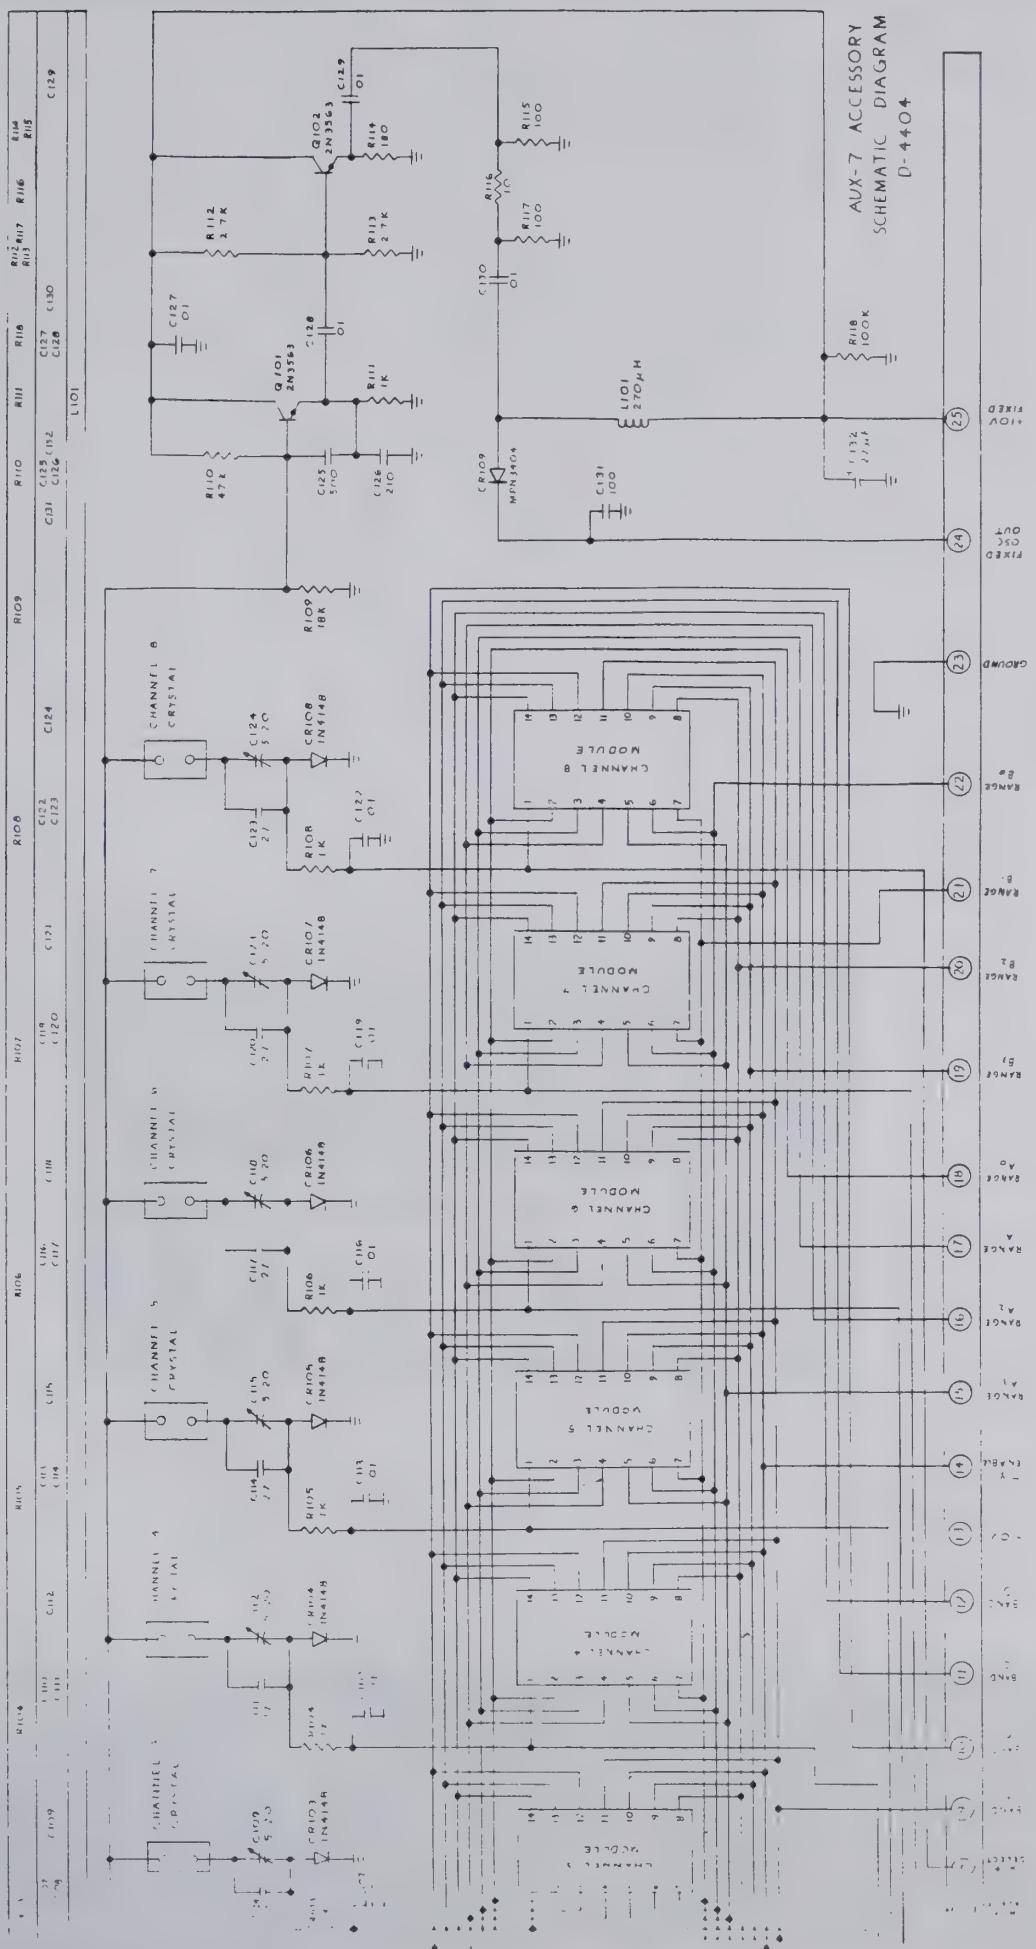

Fig. 4-4 AUX-7 Board Schematic

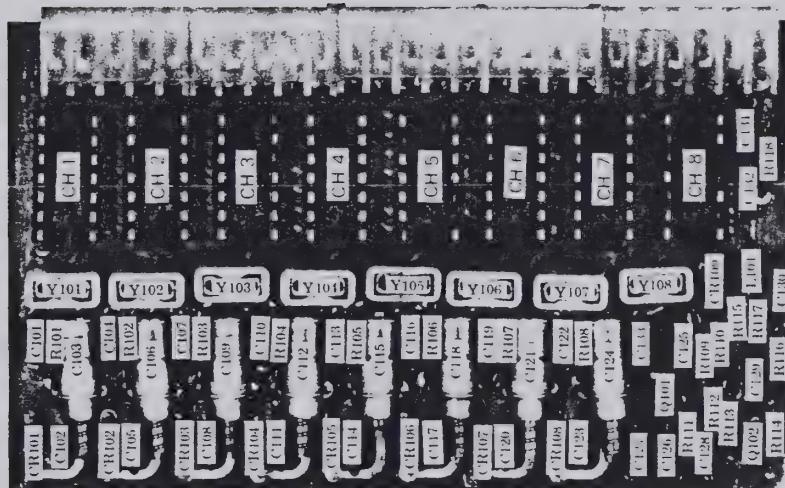

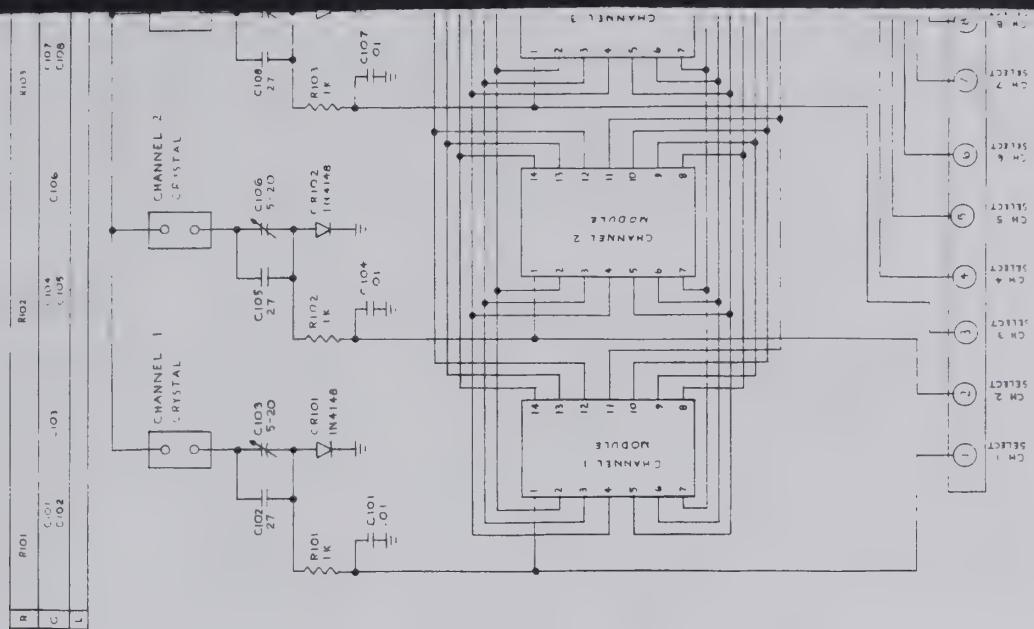

Fig. 4-3 AUX-7 Board Pictorial

### **4-3. NB-7 NOISE BLANKER**

The NB-7 Noise Blanker Board is designed for use in the TR-7. Unlike noise clippers or limiters commonly found in communication equipment, this is an advanced noise blanker which mutes the receiver for the duration of the noise pulse. Between noise pulses full receiver gain is restored, and receiver AGC is affected only by the desired signal and not by noise. The NB-7 is most effective on strong, periodic noise impulses such as automobile ignition noise and LORAN.

#### **4-3.1 CIRCUIT DESCRIPTION**

This noise blanker system is composed of the three major networks described below. Refer to the schematic diagram (figure 4-6) to follow this circuit description.

#### **4-3.2 TRANSMIT PATH**

In transmit, diode CR815 is turned on with +10T via RFC812 and RFC813 from pin 37. The 5.645 MHz double sideband transmit signal is fed to the output coax connector through C833, CR815 and C838. When CR815 is on, CR814 will be reverse biased, thus holding the receive path off.

#### **4-3.3 RECEIVE PATH**

In receive, diode CR814 is turned on with +10R via RFC810 and RFC811 from pin 24. The receive signal is applied to pin 22 and passes through the blanking gate comprised of T810, CR812, CR813, and T811, then through C830, CR814 and C838 to the output coax connector. C844 provides input matching. When CR814 is on, CR815 will be reversed biased, thus holding the transmit path off.

#### **4-3.4 NOISE PROCESSOR**

The Noise Amplifiers consist of Q810, Q811, and U810 cascaded and tuned to 5.645 MHz by L810, L811 and L812 respectively. The output of the noise amplifier string is split by C828 to the pulse detector and C827 to the noise amplifier AGC circuit. Q812 and associated circuitry comprise the noise amplifier AGC detector and amplifier. The AGC voltage is applied to gate 1 of Q810 and Q811 via R826 and R829 respectively.

The pulse detector, CR811, responds only to the positive half of the amplified bipolar input pulse. The network of R839, C831 and C835 waveshape the pulse at the base of the pulse amplifier Q813. Again, the output pulse of Q813 is shaped by R847 and C840 and is applied to the gate driver, Q814. Resistor network R842 and R843 provide fixed reverse bias for the blanking gate. Q815 is a DC switch for +10R and +10NB.

#### **4-3.5 THEORY OF OPERATION**

The 5.645 MHz receive signal, with noise pulses, is applied to pin 22. Tuned amplifiers Q810, Q811 and U810 amplify this low level signal up to a high level to drive the pulse detector CR811. This detector responds only to the positive going portion of each noise pulse from the output of U810. Following the detector is an RC network which shapes the pulses for driving the level shifter Q813. Again, on the output of Q813 is still another RC network for waveshaping. The gate driver transistor Q814 responds to the negative going pulse from Q813 which allows the blanking gate to turn off, thus muting the receive path and blanking the noise pulse.

Since the noise amplifiers run such high gain, Q812 and associated circuitry comprise an AGC loop to maintain a near constant output level to the detector. This allows detection and processing of very weak as well as very strong noise pulses without degrading the blanking action.

#### **4-3.6 NB-7 NOISE BLANKER-ALIGNMENT**

The NB-7 is easily aligned via the following procedures:

Equipment Required: High Input Impedance VTVM

The following parts from the TR-7 Maintenance Kit:

- 1 6-pin extender card
- 1 4-pin extender card
- 1 tuning tool

- 1) Remove NB-7 per Installation instructions 1 through 4.
- 2) Carefully install extender cards making sure they properly match the connectors on the NB-7 and the pins in the TR-7 card cage.

- 3) Connect coax from IF Selectivity card to the coax receptacle on top of the NB-7. Note if coax will not reach - Remove IF Selectivity card and cut wire tie on coax to facilitate connection of coax.
- 4) Turn TR-7 on and depress calibrator switch. Tune in calibrator signal. Put Mode switch in CW, Band switch at 14 MHz.
- 5) Refer to figure 1 and connect VTVM to test pad. Depress NB switch to activate Noise Blanker.
- 6) Tune L810, L811 and L812 for maximum DC voltage.
- 7) Remove VTVM and turn off TR-7.
- 8) Remove NB-7 and extender cards.
- 9) Reinstall NB-7 as per Installation steps 5 through 9.

PS-7 Power Supply

## NOTE:

Care should be taken to insure that adequate clearance is provided around the PS-7 for proper circulation of air, especially around the heat sinks. Also, avoid placing books, papers, or other pieces of equipment on top of the unit as overheating could result.

## PS-7 POWER SUPPLY, MODEL 1502

### General Description

The PS-7 is a 13.6 volt DC regulated power supply capable of delivering up to 25 amps of continuous current. Excellent voltage regulation is provided by a silicon monolithic integrated circuit and associated circuitry. Output voltage and current are adjustable with internal controls which have been factory set to provide 13.6 volts at up to 25 amps. Other features include short circuit and overvoltage protection and programmable primary voltages. An auxiliary 13.6 VDC output is provided on the rear panel and is fused internally at 1 amp. Primary voltages of 100, 120, 200, and 240 VAC, 50-60 Hz may be used with the PS-7 and may be quickly changed via the programming switches. For demanding duty cycles, such as extended RTTY or SSTV transmission, the model 1529 FA-7 Cooling Fan is recommended for additional cooling, especially at ambient temperatures above 25°C.

### Current Overload Protection

When the PS-7 is subjected to a current overload or short circuit condition, the regulator circuit will automatically shut down. The unit may be reset by momentarily switching the ON-OFF switch on the TR-7 to OFF or by removing the AC primary voltage to the PS-7. The power transformer is protected by an 8 ampere type ABC fuse on primary voltages of 100 or 120 VAC or a 4 ampere type MTH fuse on 200 or 240 VAC. Refer to Figure 1 for location on the rear panel. *This fuse should be replaced with another fuse of the same type and rating.* The auxiliary DC output is internally fused with a 1 amp type MDL fuse. This is located inside the unit, on the regulator P.C. board. *This fuse should be replaced only with another fuse of the same type and rating.*

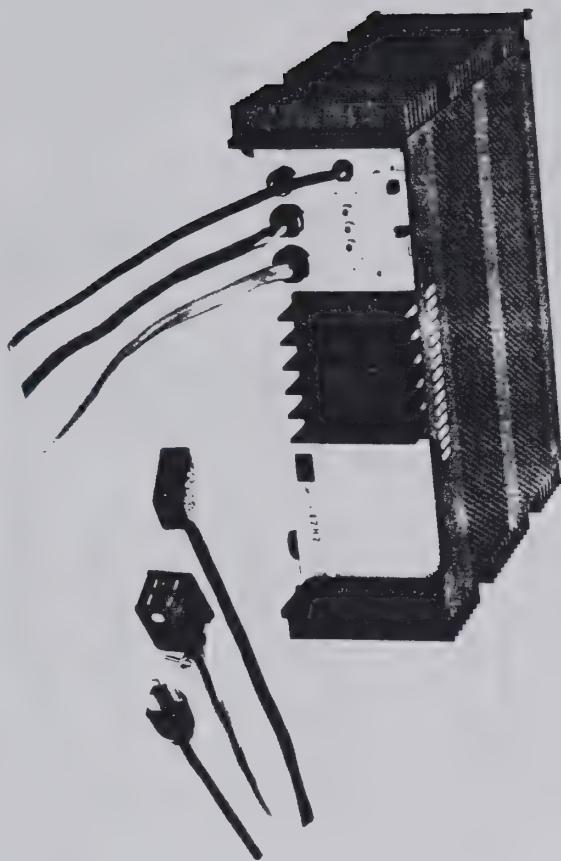

Fig. 1—Rear Panel Controls and Connections

### **Overvoltage Protection**

If the PS-7 regulator section should fail or one of the pass transistors should short, the unit will automatically shut down. If the DC output voltage should soar above 16 VDC, an SCR crowbar clamps the output to ground to protect the load and open the primary fuse. *This fuse should be replaced with another of the same type and rating after determining the cause of the overload.*

### **Linear Amplifier**

All necessary connections for use with a linear amplifier are provided on the rear panel of the PS-7. Refer to Figure 3. Connect a patch cord to the ALC Jack and the VOX Jack.

### **Factory Service**

The PS-7 will be checked and serviced at the factory for a nominal fee if there is no evidence of tampering. Transportation charges are extra. Any necessary repairs will be made on a time and material basis. Please write or call the factory for authorization before returning the unit for service. Requests for authorization should be addressed to:

## PS-7 POWER SUPPLY

### SPECIFICATIONS

**AC INPUT:**

100, 120, 200, or 240 Volts AC,  
 $\pm 10\%$  50-60 Hz.

**DC OUTPUT:**

13.6 Volts DC with less than 3mV RMS  
 of ripple at 25 amperes load.

**DC CURRENT:**

25 amperes continuous. (at 25°C. ambient)

**DC AUX VOLTS:**

13.6 VDC regulated.

**DC AUX CURRENT:**

1 ampere maximum.

**CONNECTORS:**

- Aux DC Phono Jack
- ALC Phono Jack
- VOX Contact
- Fan AC
- Ground Connection
- Phono Jack

**DIMENSIONS:**

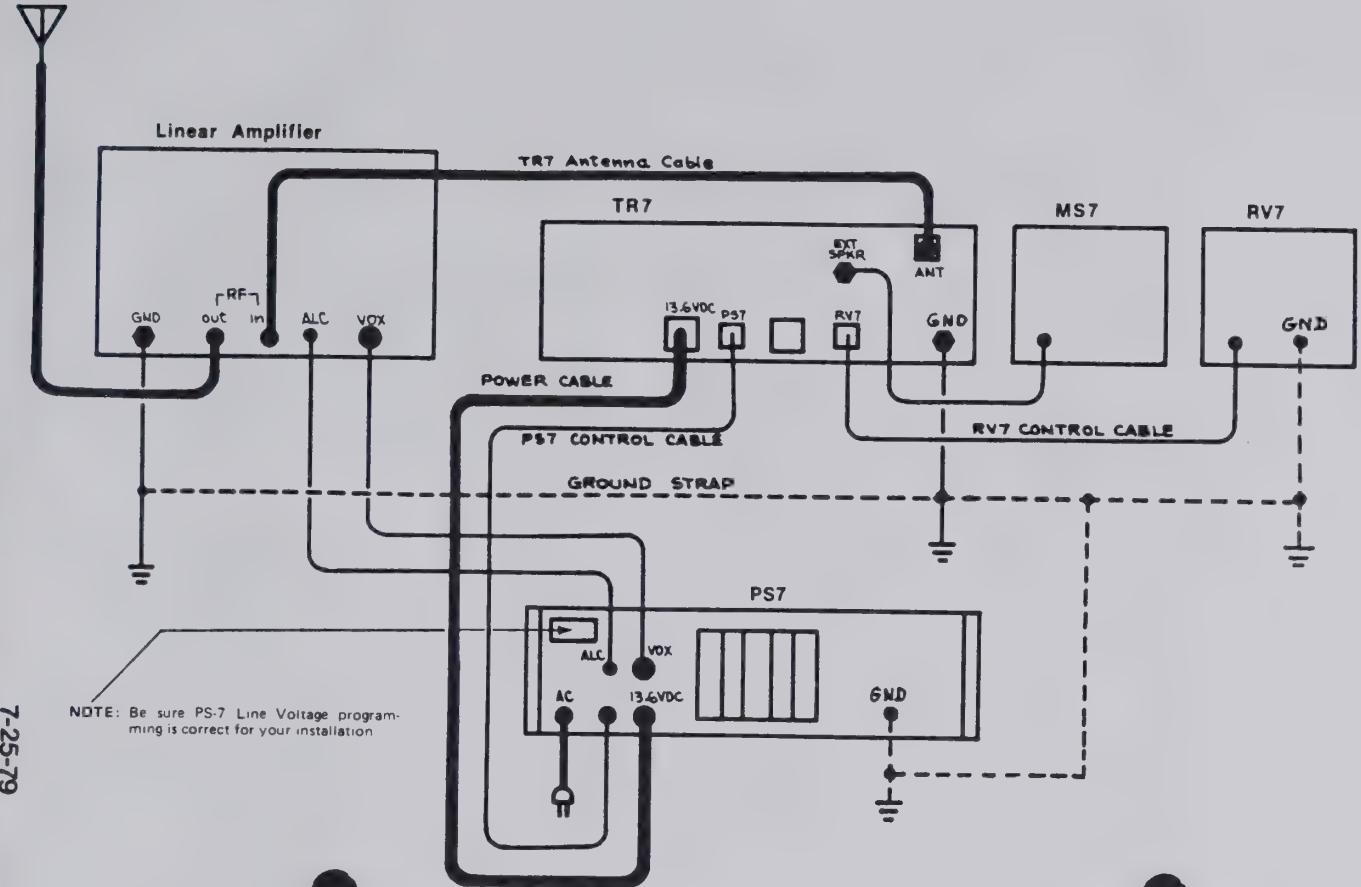

Width—13 3/4" (34.93 cm.)  
 Height—5 1/4" (13.34 cm.)  
 Depth—12 1/2" (31.75 cm.)

**WEIGHT:**

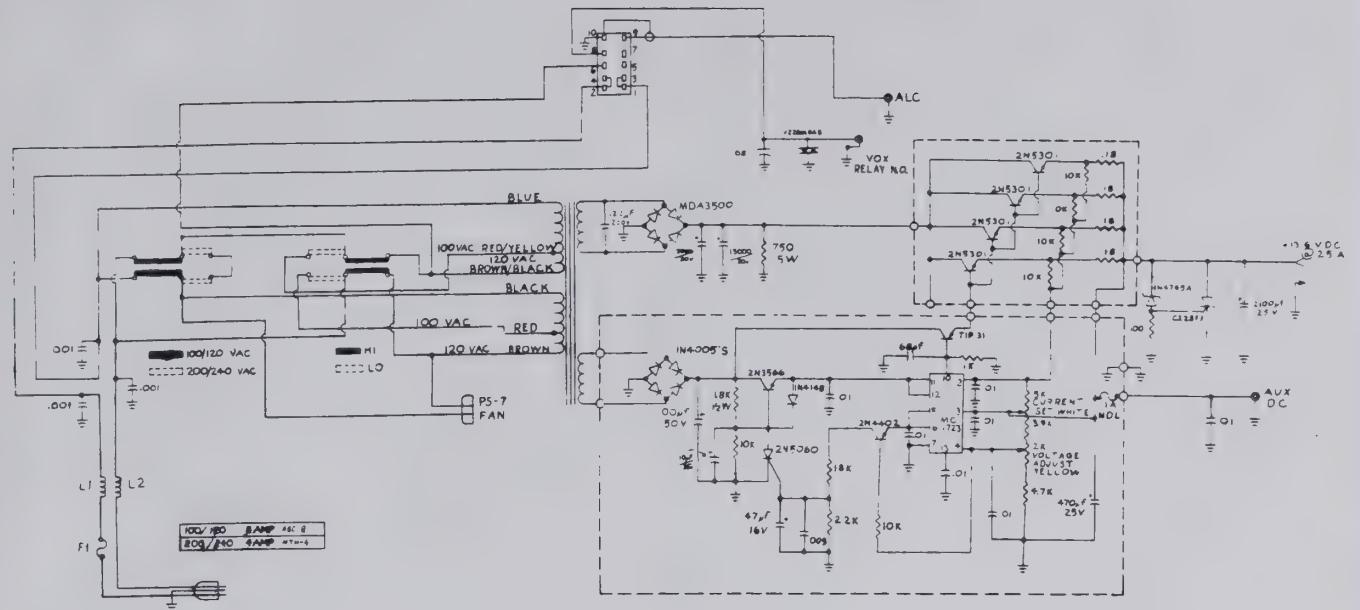

32 1/4 lbs. (15 kg)

\*25 amperes continuous @ up to 40°C ambient with optional  
 FA-7 FAN (Model 1529)

NOTE: Be sure PS-7 Line Voltage programming is correct for your installation

RV-7 REMOTE VFO  
MODEL 1338

General Description

The RV-7 is designed for use with the TR-7 and offers the operator a high degree of frequency control flexibility. The RV-7 can be employed for transmit, receive or transceive frequency control or can be turned off to allow transceive frequency control from the TR-7. For added convenience, the TR-7 RIT control line is applied to the RV-7 in the receive mode. A spot switch allows the RV-7 and TR-7 PTOs to be zero beat in split mode operation. The unit is housed in a cabinet which is styled to match the TR-7.

## Operation

The RV-7 has three controls: the main tuning dial, the function select control and spot switch.

The main tuning control determines the frequency of the VFO and is calibrated in exactly the same fashion as the transceiver VFO. The RV-7 function control has four positions: OFF, RCV, RCV/XMIT, and XMIT. The green LED indicates when the RV-7 is controlling the frequency of the TR-7.

In the *OFF* position, the transceiver will transceive normally using the internal PTO.

In the *RCV* position, the green LED will light in receive, indicating that the RV-7 PTO is enabled. It will extinguish in transmit. In this position, the RV-7 controls only the received frequency. The PTO in the TR-7 controls the transmit frequency.

In the *RCV/XMIT* position, both the transmit and receive frequencies are determined by the RV-7. The TR-7 PTO is disabled. The green LED will light indicating that the RV-7 has control both in transmit and receive.

In the *XMIT* position, the RV-7 controls only the transmit frequency. The receive frequency is determined by the TR-7 PTO. The green LED will light only when the TR-7 is in transmit.

To install the RV-7, simply connect the control cable to the 8 pin connector located on the rear of the TR-7. A 4 foot cable is provided for ease of location by the operator. See the TR-7 manual for the location of this connector.

## Installation

The SPOT button is used for zero beating the RV-7 PTO with the TR-7 PTO. When the SPOT switch is depressed, the green LED will light indicating the RV-7 PTO is enabled. Be sure when using the SPOT button that the RIT is off. The RIT sensitivity between the PTOs may not be equal leading to errors in the zeroing of the two PTOs. When in SPOT, some spurious signals will be created, be sure to pick the loudest, widest signal when zeroing the two PTOs. The TR-7 will not transmit with the SPOT switch depressed.

## Service Data

The RV-7 will be checked and aligned at the factory for a nominal fee if there is no evidence of tampering. Transportation charges are extra. Any necessary repairs will be made on a time and materials basis. Please write or call the factory for authorization before returning your unit for alignment or service. Address your requests for authorization to:

**R. L. DRAKE COMPANY**  
540 Richard Street  
Miamisburg, OH 45342  
ATTN: Customer Service Department  
Telephone: (Area Code 513) 866-3211  
Telex: 288-017

### Alignment

The RV-7 is very carefully aligned at the factory and should require no further adjustment. If a tracking error in the VFO is noted, the unit should be returned to the factory.
